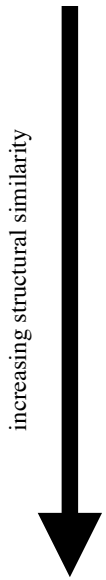
Handedness

SCOP -- a hierarchy

- http://scop.berkeley.edu



(1) class

(2) fold

(3) superfamily

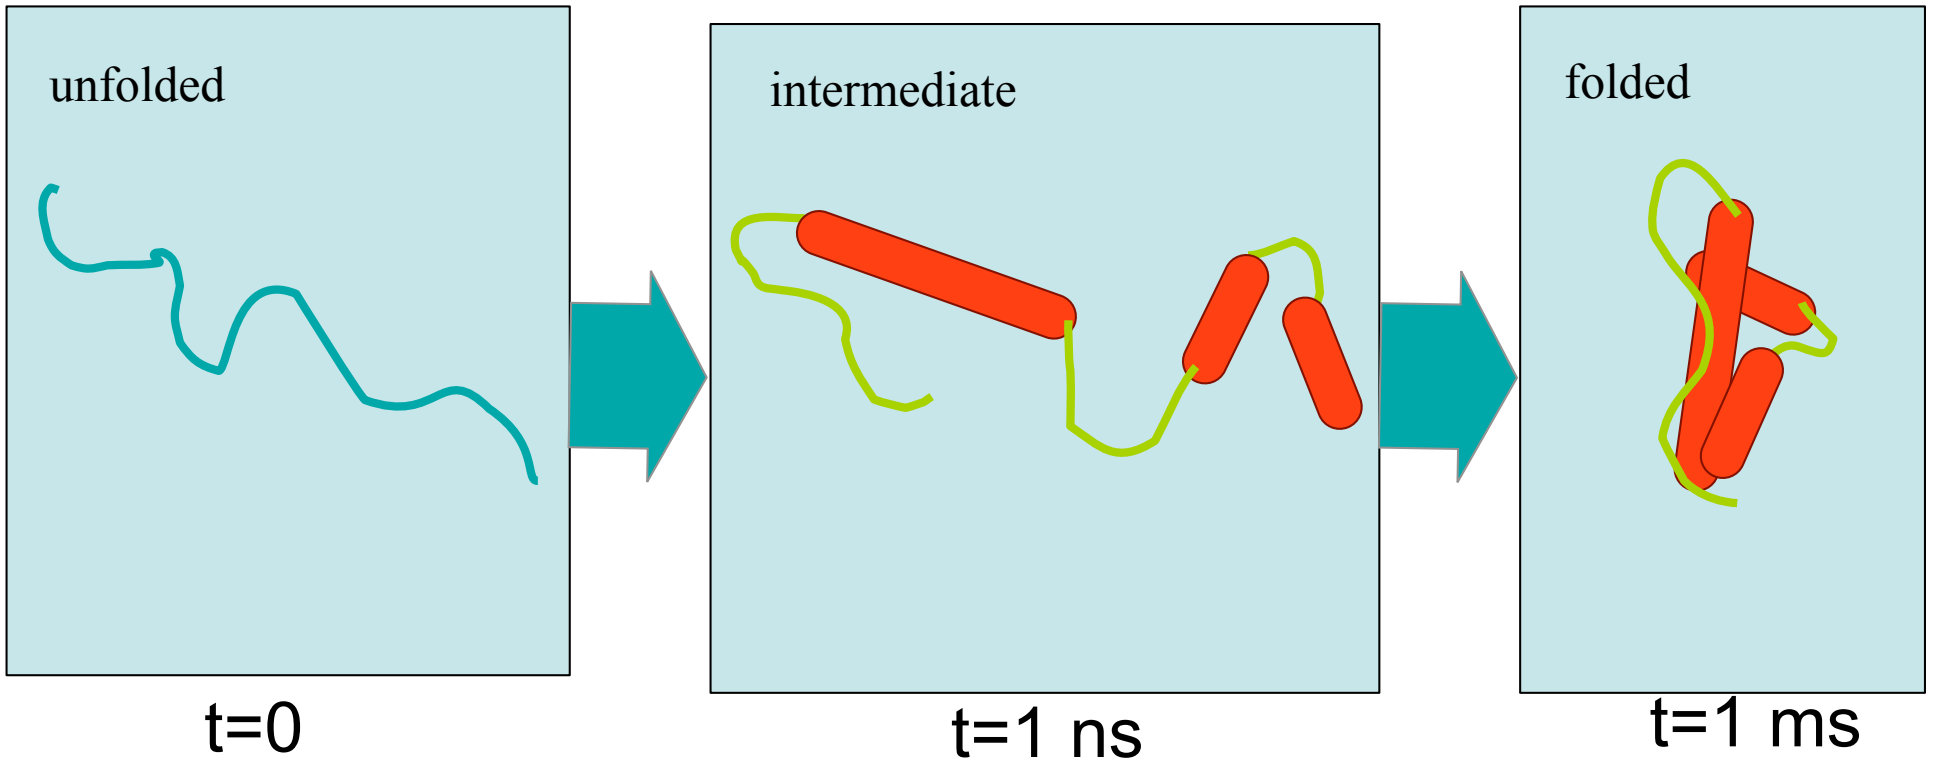
(4) family

(5) protein

(6) species

SCOP's hierarchy is sequence centered

Folding -- another hierarchy?



t = time after leaving the ribosome

More about protein folding in later lectures

Structural classification viewed along the folding hierarchy

Classification

Secondary structure

Local structure

Super-secondary structure

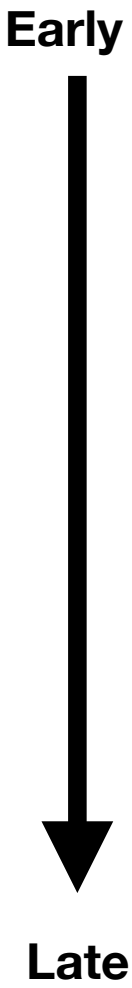
Domains (tertiary structure)

Side chain rotamers

Domain-domain interactions

Quaternary structure

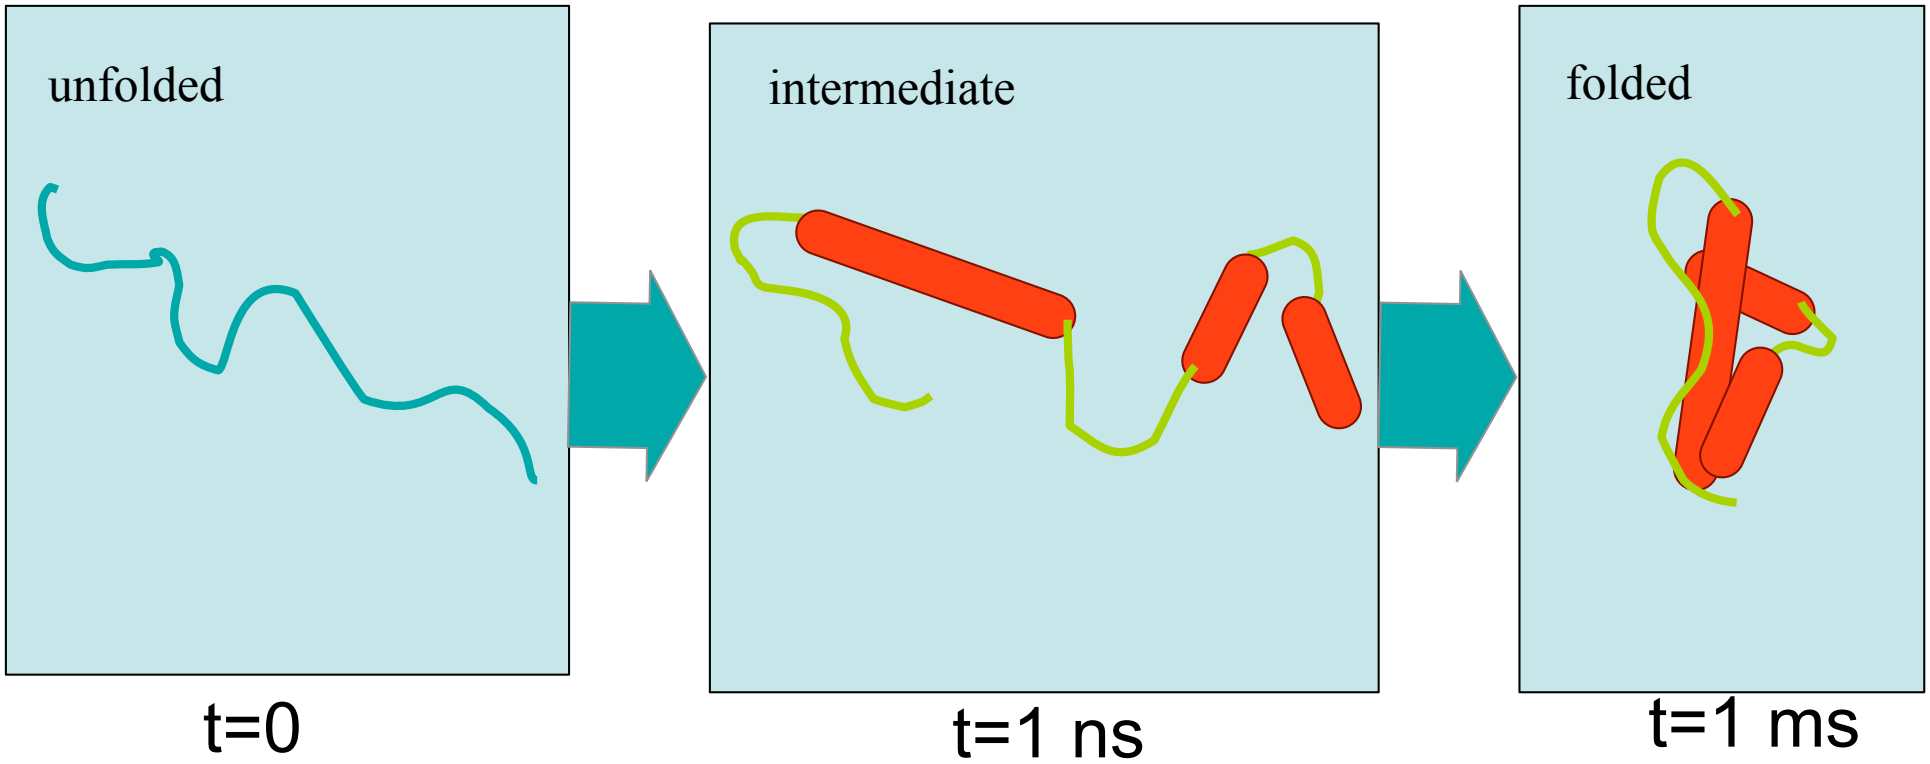
Super-quaternary structure



Why does local sequence predict structure?

Early in the process of folding (nsec timescale)

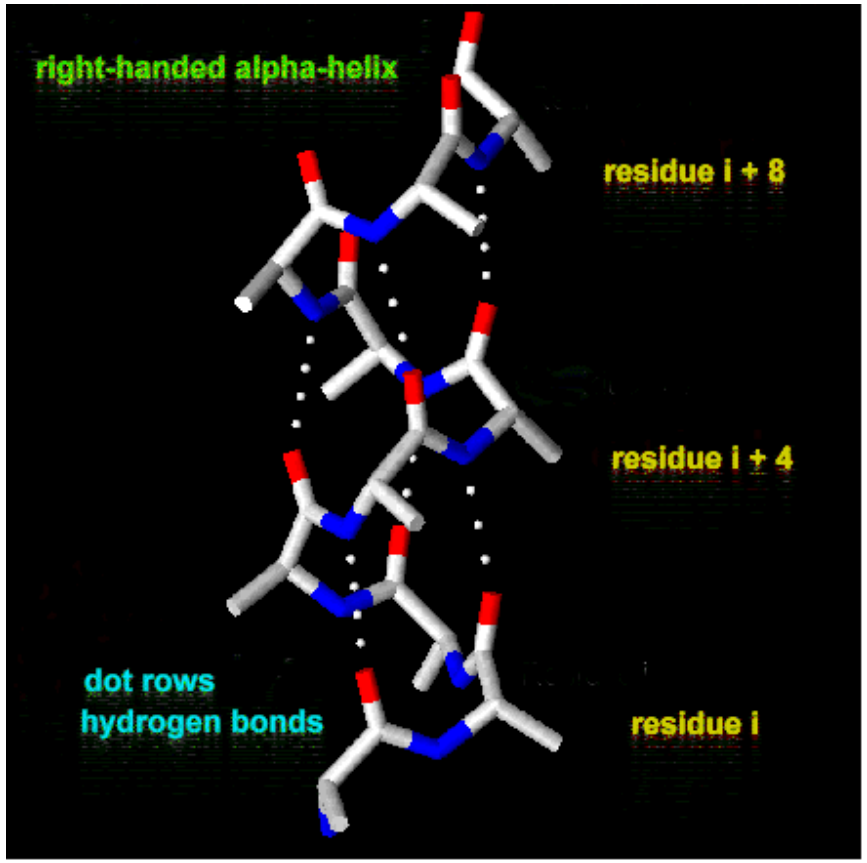
local structures form in the polypeptide chain which guide the formation of tertiary structure.



Alpha helix

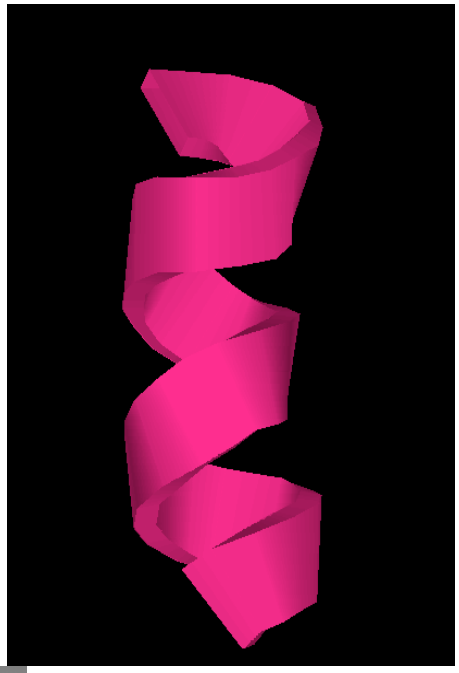
Right-handed helix. H-bond is from the oxygen at *i* to the nitrogen at *i+4*. α-helices have an overall dipole because the H-bonds are all in the same direction. Must be > 3 residues.

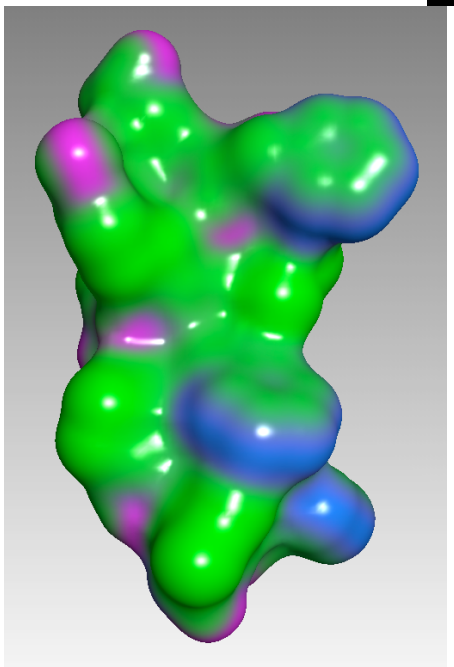
H-bond rule for donor to acceptor (NH->O): i to i+4



dipole

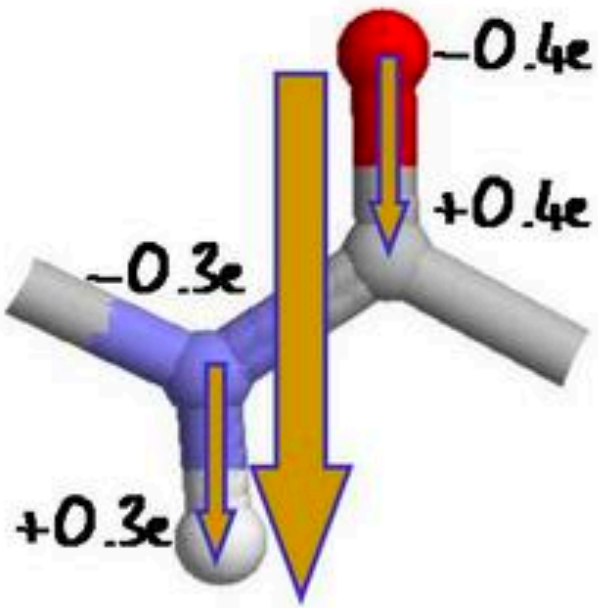
right-handed





Helices do not look “cylindrical”.

ALPHA-HELIX DIPOLE 1



- The peptide group has a strong dipole moment due to partial charges on NH and CO groups.

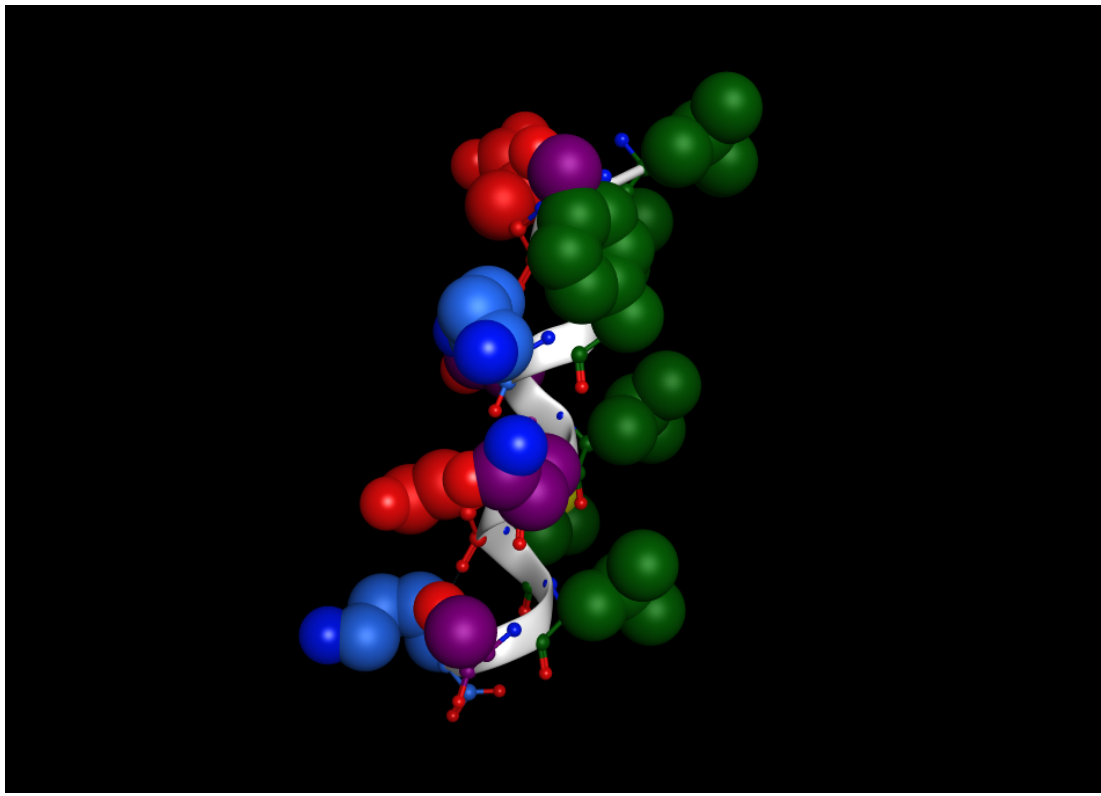
https://web.stanford.edu/class/sbio228/public/lectures/lec2/Lecture2/The_Alpha_Helix/images/Alpha-Helix_Dipole_1.jpg

Sequence pattern for the amphipathic alpha helix

- nppnnpp,
  where n = non-polar, p = polar
- Example:

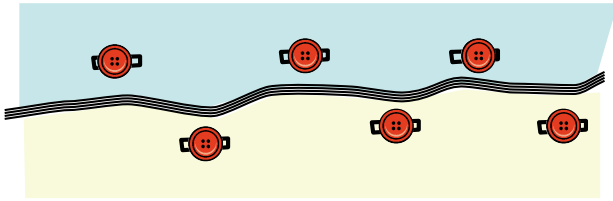
  LSELFKNLQDMLSK

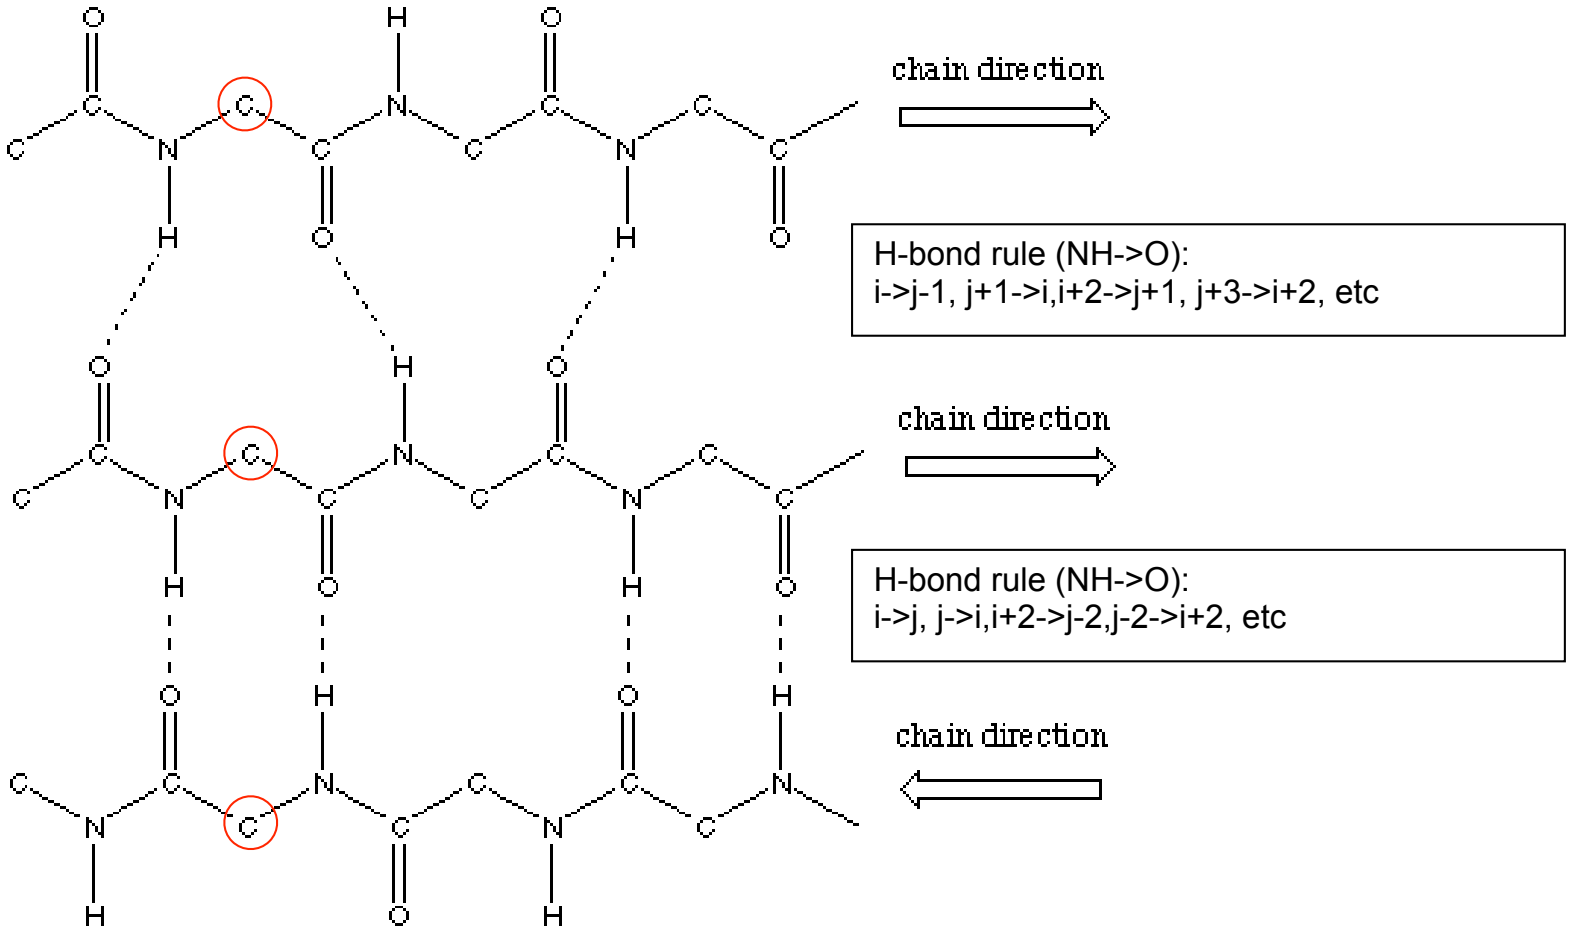
Hydrophobic all on one side



The helix is held together by the hydrophobic effect.
Sticks to other amphipathic helices.

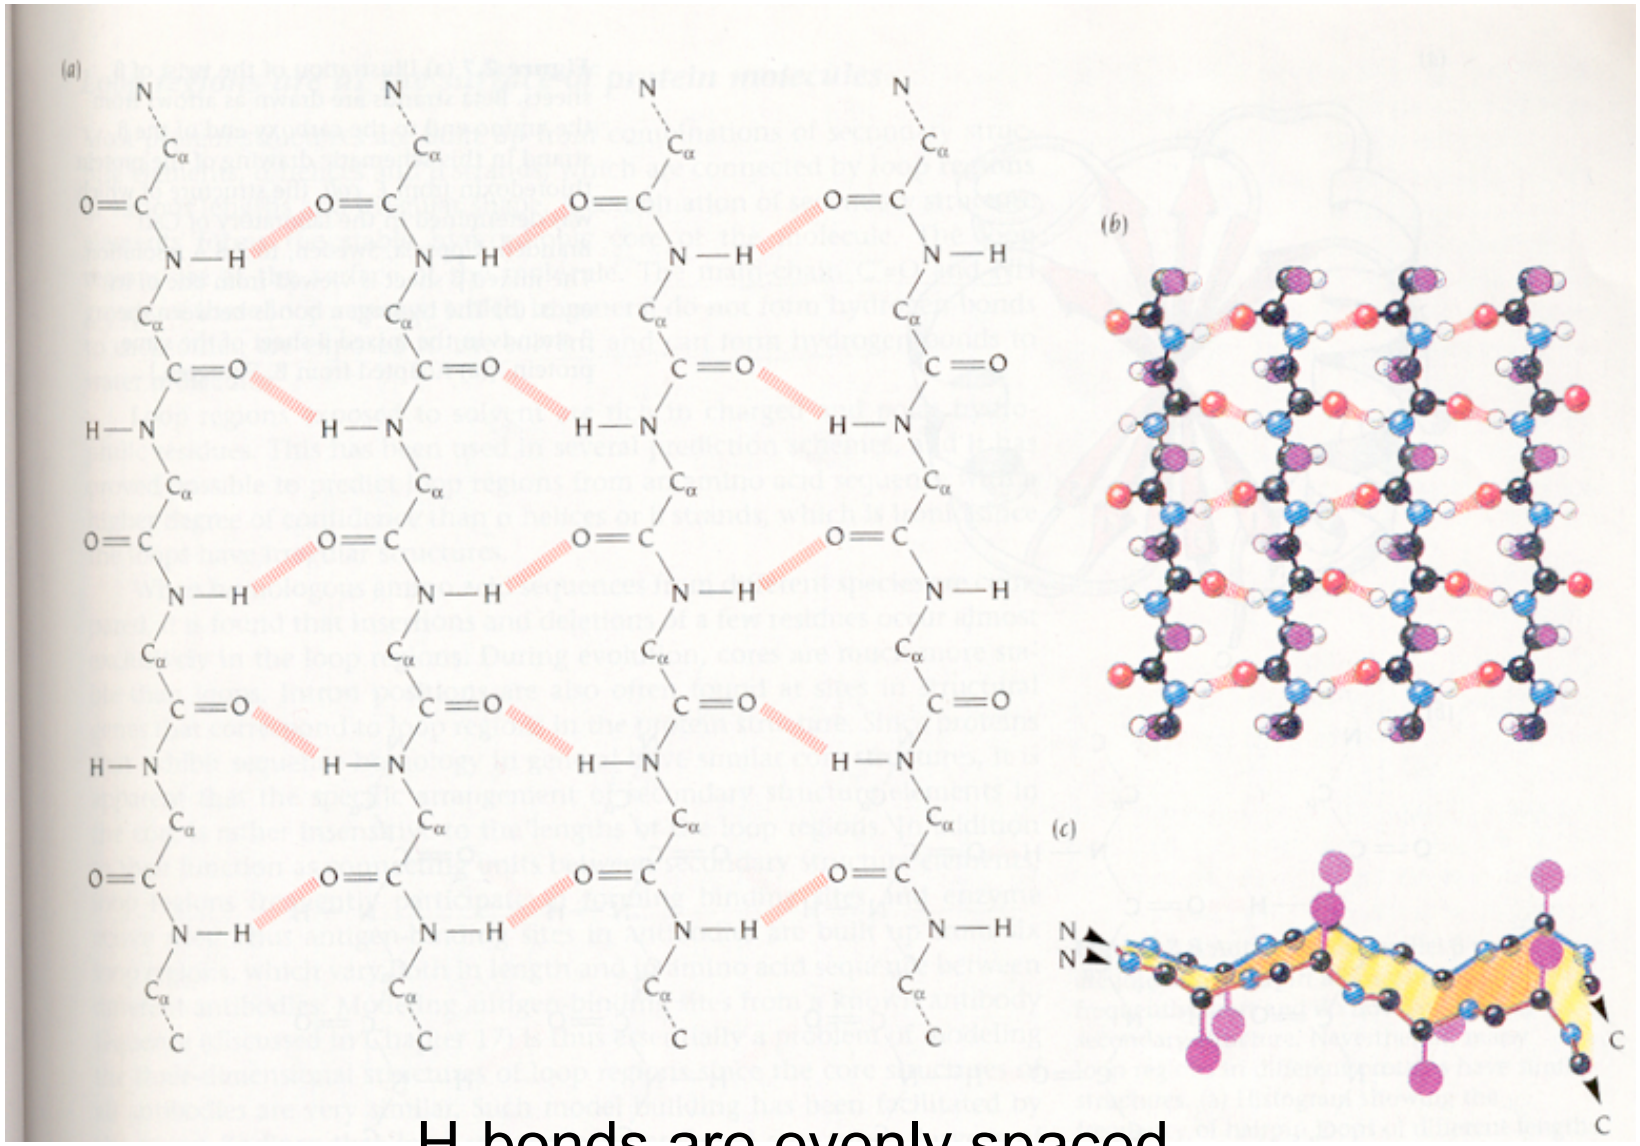
beta sheets





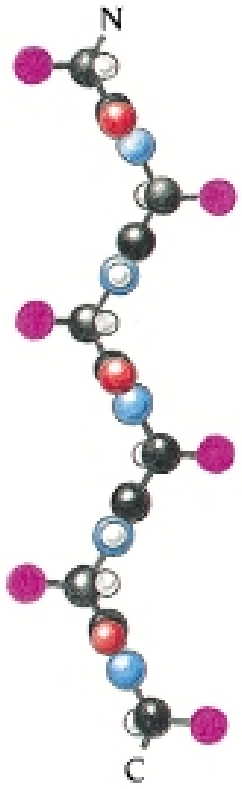
In both parallel and anti-parallel,
sidechains alternate above and below the plane of the sheet.

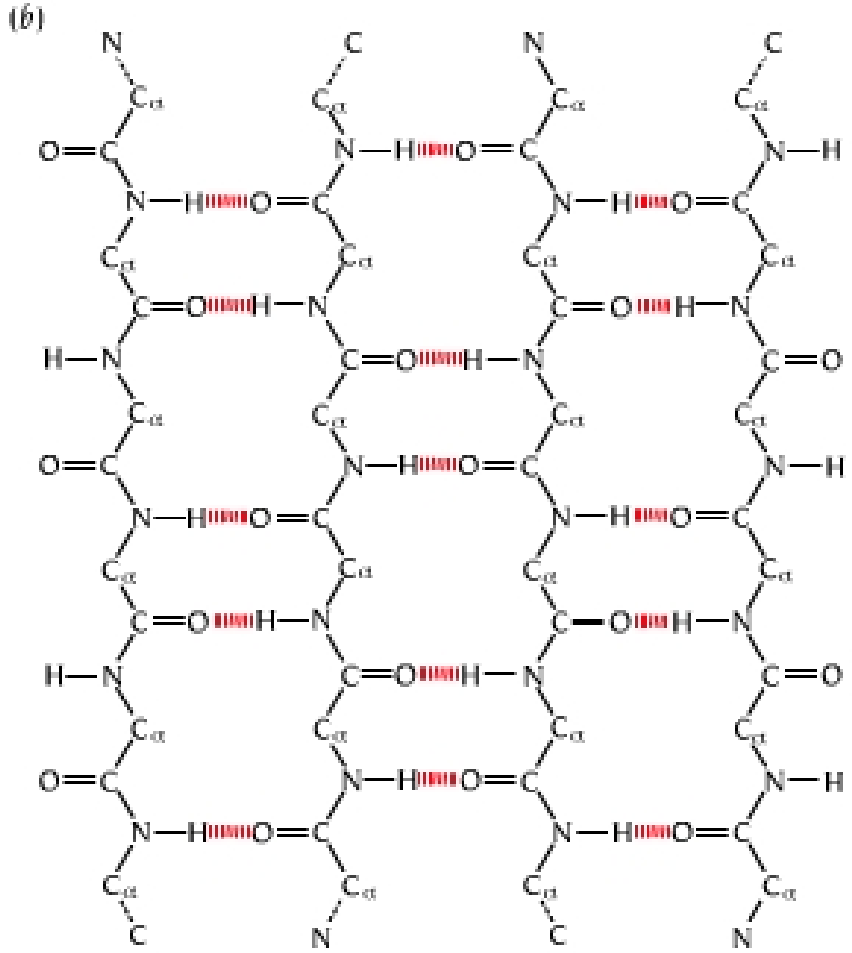
Parallel beta sheet



H-bonds are evenly spaced.
H-bonds are not 90° to the chain.

Anti-parallel beta sheet

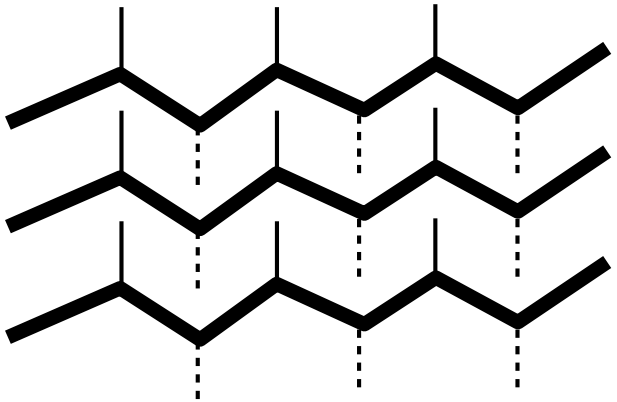




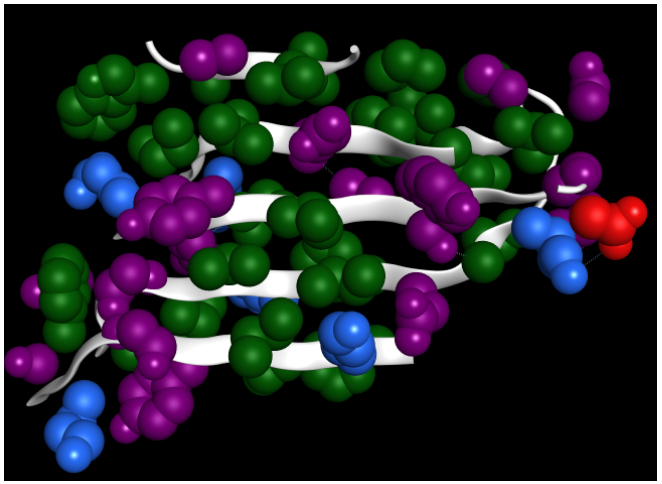
H-bonds are unevenly spaced.
H-bonds are 90° to the chain.

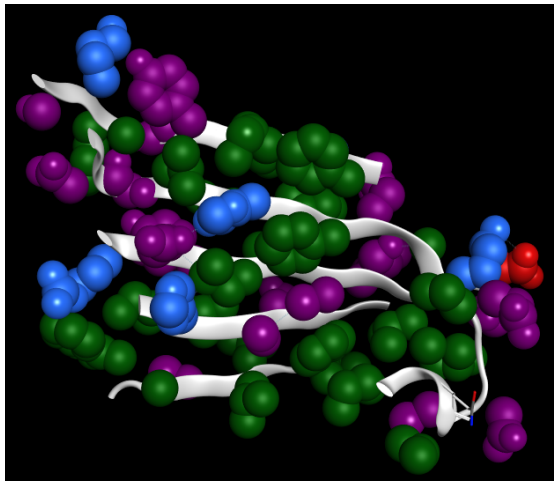
Sequence patterns for beta sheet

- npnp, where n=non-polar, p=polar
- nnnn



Non-polar residues (green, purple) mostly on the face.





Charged residues (blue, red) mostly on the ends.

Secondary structure using matrices

An H-bonding pattern can be expressed using "augmented" matrix notation.

next H-bond donor
next H-bond acceptor

=

multiply by donor	multiply by acceptor	add to donor
multiply by donor	multiply by acceptor	add to acceptor

X

current H-bond donor
current H-bond acceptor

For example, for an alpha helix....

150
146

=

1	0	1
1	0	-3

X

149
145

In a helix, donor NH is always +4 to acceptor O.

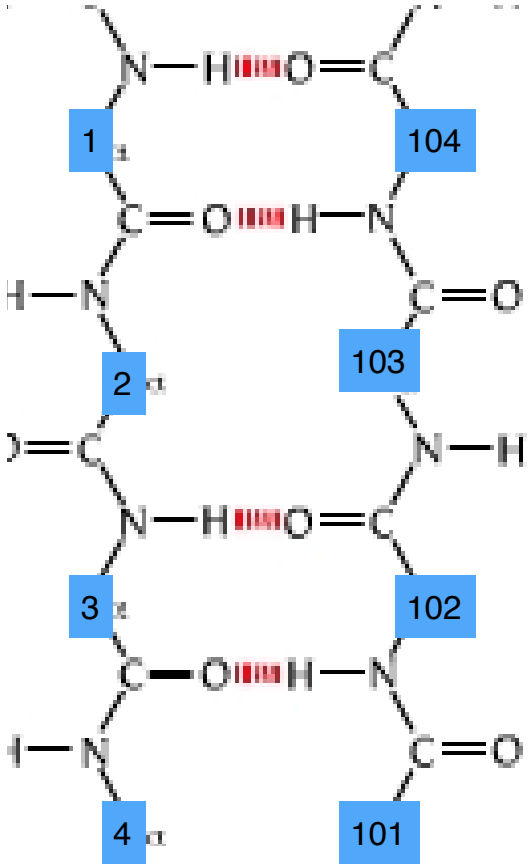
Secondary structure using matrices: antiparallel sheet

handshake

$$\left[\begin{array}{cc|c} 0 & 1 & 0 \\ 1 & 0 & 0 \end{array}\right]$$

skip

$$\left[\begin{array}{cc|c} 0 & 1 & 2 \\ 1 & 0 & -2 \end{array}\right]$$



Use the augmented matrices to find the next H-bond before/after (donor,acceptor)=(102, 3) in a antiparallel sheet

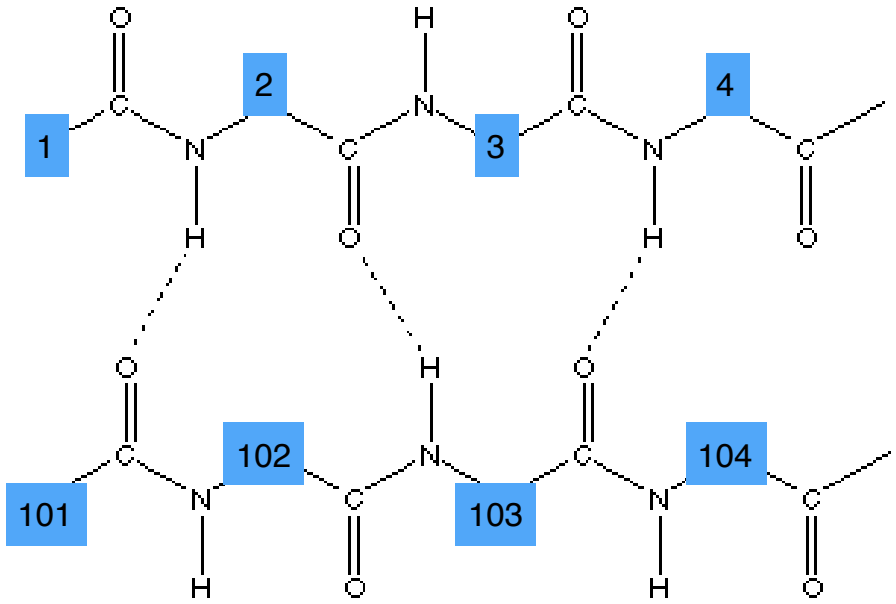
Secondary structure using matrices: parallel sheet

C

0	1	2
1	0	0

N

0	1	0
1	0	-2



Use the augmented matrix to find the next H-bond before/after (donor,acceptor)=(103, 2) in a parallel sheet

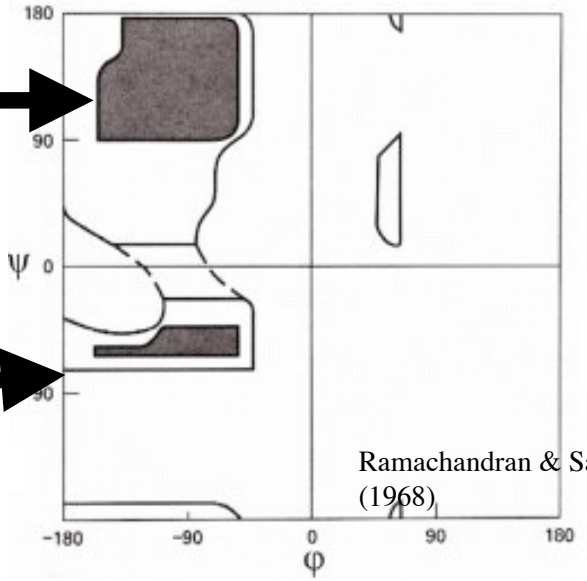
The Ramachandran Plot

beta sheet

-180° < Φ < 0°
90° < Ψ < 180°

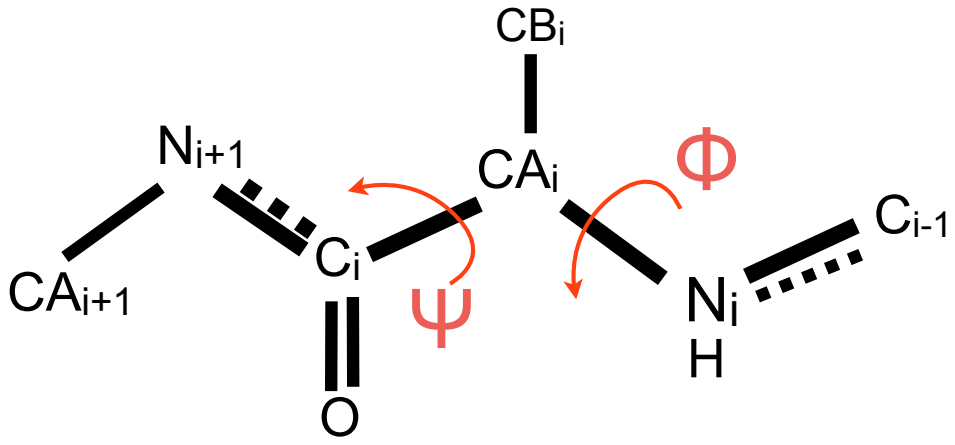
alpha helix

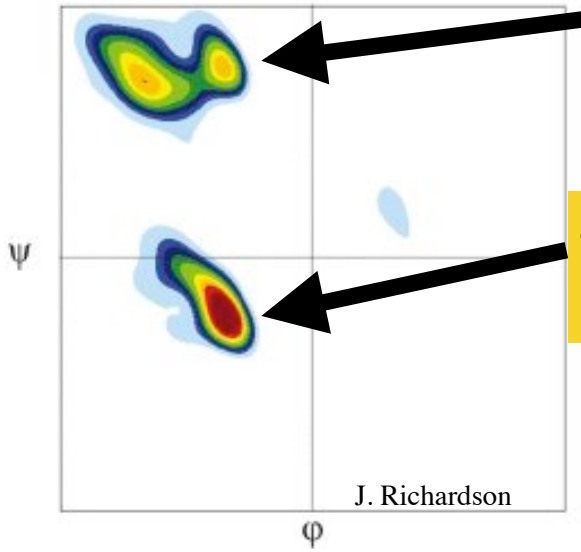
-100° < Φ < -40°
-80° < Ψ < -30°



Ramachandran & Sasisekharan (1968)

(a)





J. Richardson

Φ = -139°
Ψ = 135° β

Φ = -58°
Ψ = -47° α

Predicting secondary structure from primary structure

assumes

1. Secondary structures have sequence patterns
2. Those patterns are conserved across homolog proteins.

predicting burial

- Early methods for predicting the structure of a protein used the chemical characteristics of amino acids -- hydrophobic versus hydrophilic. If a stretch of aminoacids was hydrophobic, it was most often found in the core of the protein, and the opposite was true if a stretch was hydrophilic. Two scales were proposed -- Kyte-Doolittle and Hopp-Woods.

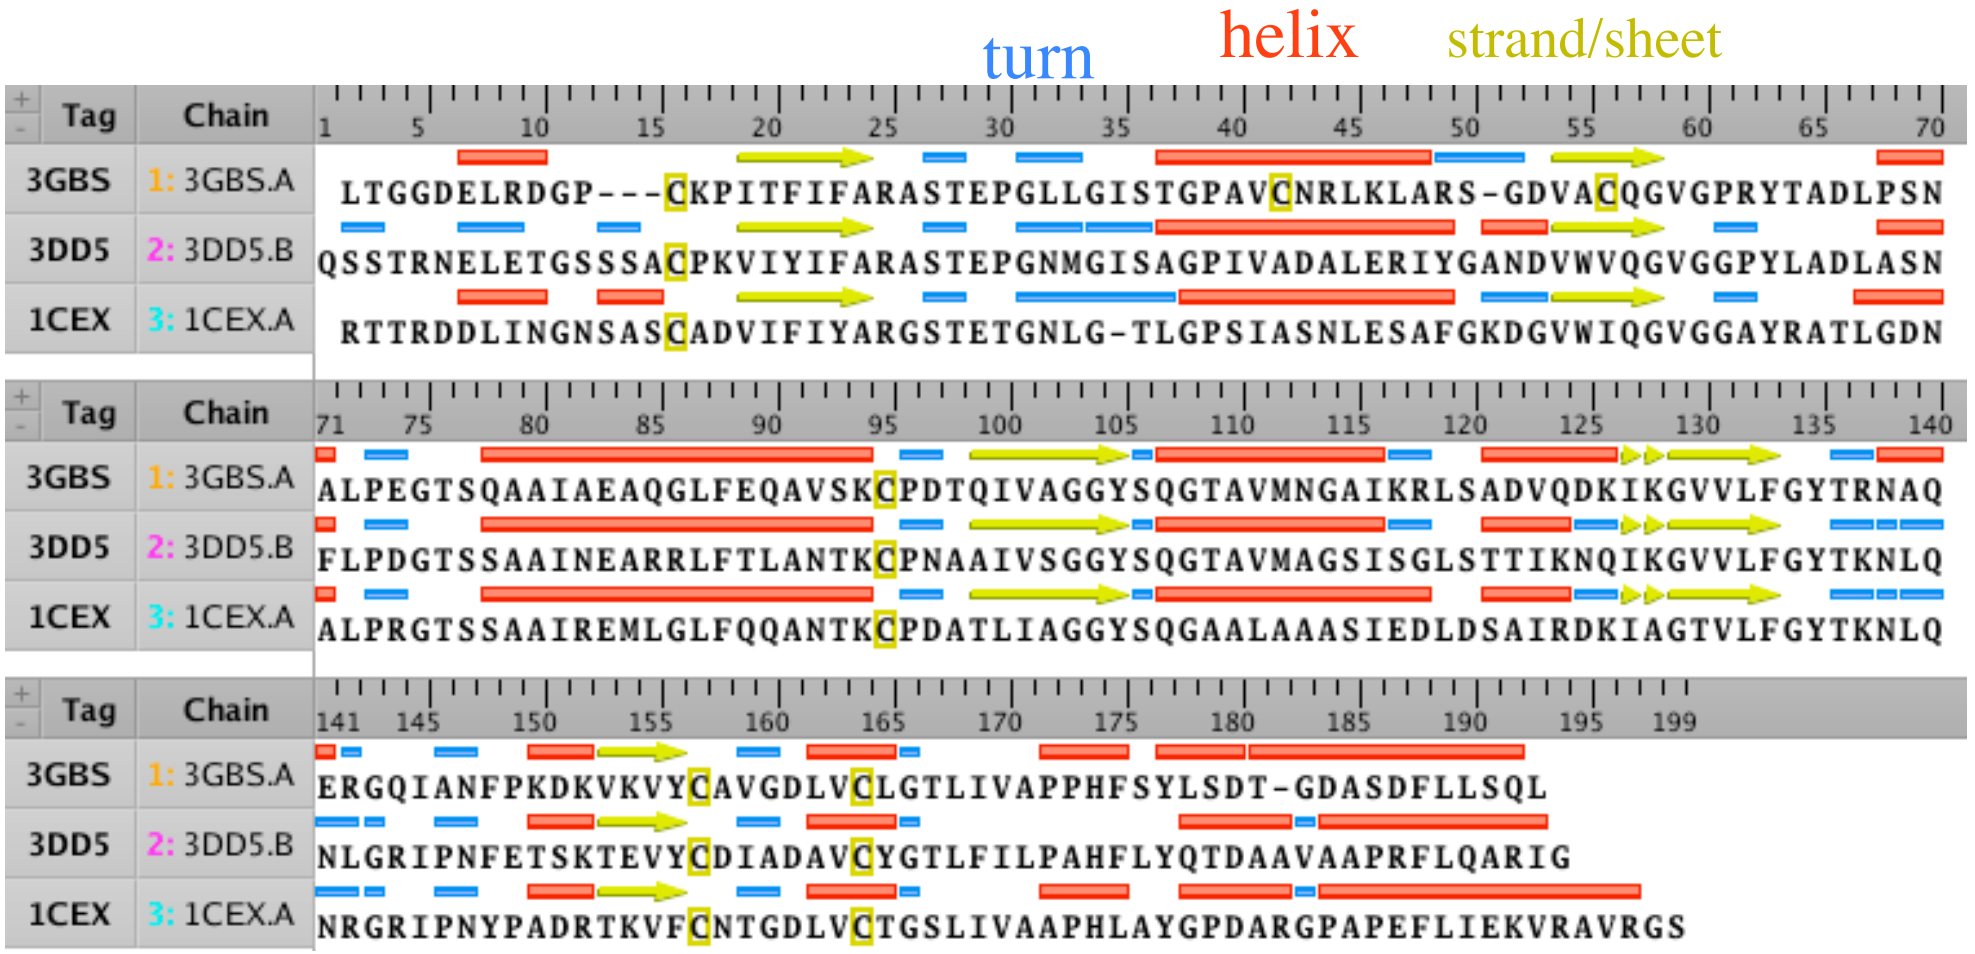
	Kyte-Doolittle	Hopp-Woods
Alanine	1.8	-0.5
Arginine	-4.5	3.0
Asparagine	-3.5	0.2
Aspartic acid	-3.5	3.0
Cysteine	2.5	-1.0
Glutamine	-3.5	0.2
Glutamic acid	-3.5	3.0
Glycine	-0.4	0.0
Histidine	-3.2	-0.5
Isoleucine	4.5	-1.8
Leucine	3.8	-1.8
Lysine	-3.9	3.0
Methionine	1.9	-1.3
Phenylalanine	2.8	-2.5
Proline	-1.6	0.0
Serine	-0.8	0.3
Threonine	-0.7	-0.4
Tryptophan	-0.9	-3.4
Tyrosine	-1.3	-2.3
Valine	4.2	-1.5

Hopp TP and Woods KR: Prediction of protein antigenic determinants from amino acid sequences. Proc Natl Acad Sci USA 78:3824, 1981.

Kyte J and Doolittle RF: A simple method for displaying the hydropathic character of a protien. J Mol Biol 157:105, 1982.

Try it: http://www.vivo.colostate.edu/molkit/hydropathy/

Secondary structure is strongly conserved among even remote homologs.

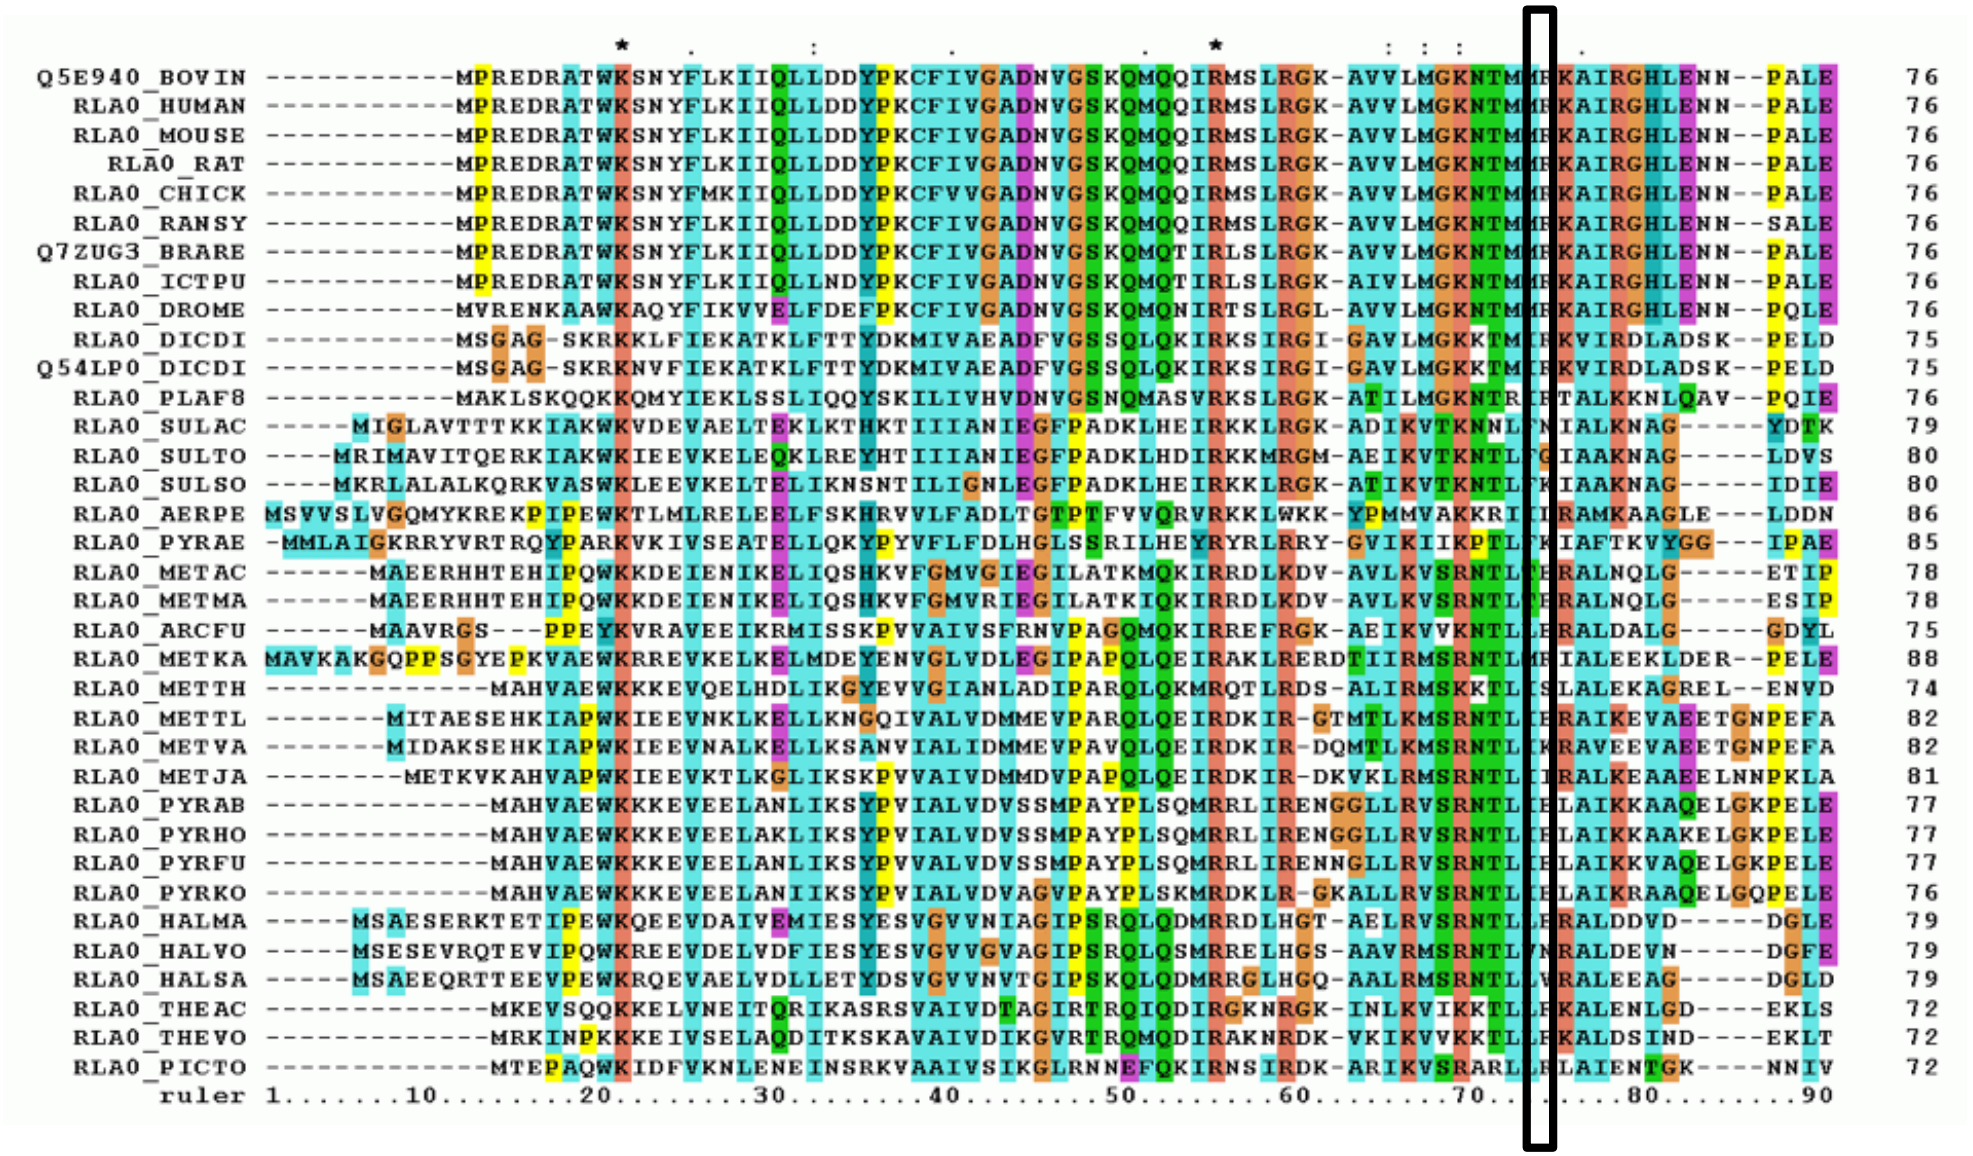


cutinases, 48 - 53% sequence identity.

Amino acid sequence profiles have patterns in them

- Positions in homologs conserve location, side chain conformation, packing environment.
- Evolution has sampled the low energy ways to fill each position.
- Multiple sequence alignments inform us about the nature of the position.
  - buried vs exposed.
  - alpha vs beta vs loop

First make a multiple sequence alignment



Each position in a MSA is a column of AA's representing the evolutionary history of one position.

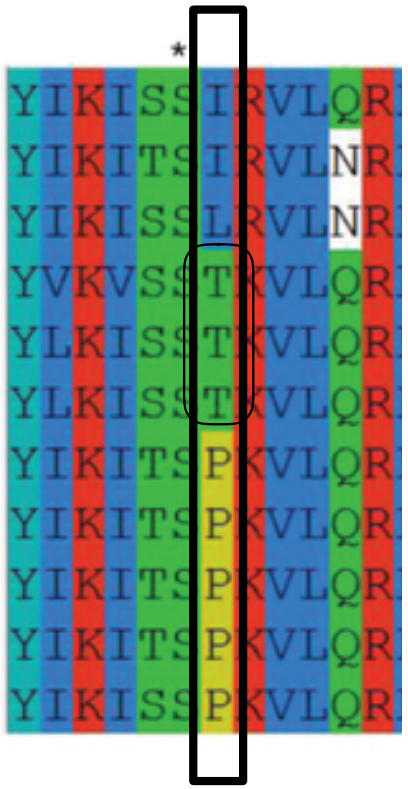
Sequence profiles are calculate from MSAs

$$P(T|7) = \frac{\sum_{i \,\forall\, S_{(7)}=T} w_i}{\sum_{all\ i} w_i}$$

Prob of Thr@ position 7 is the sum of the weights.

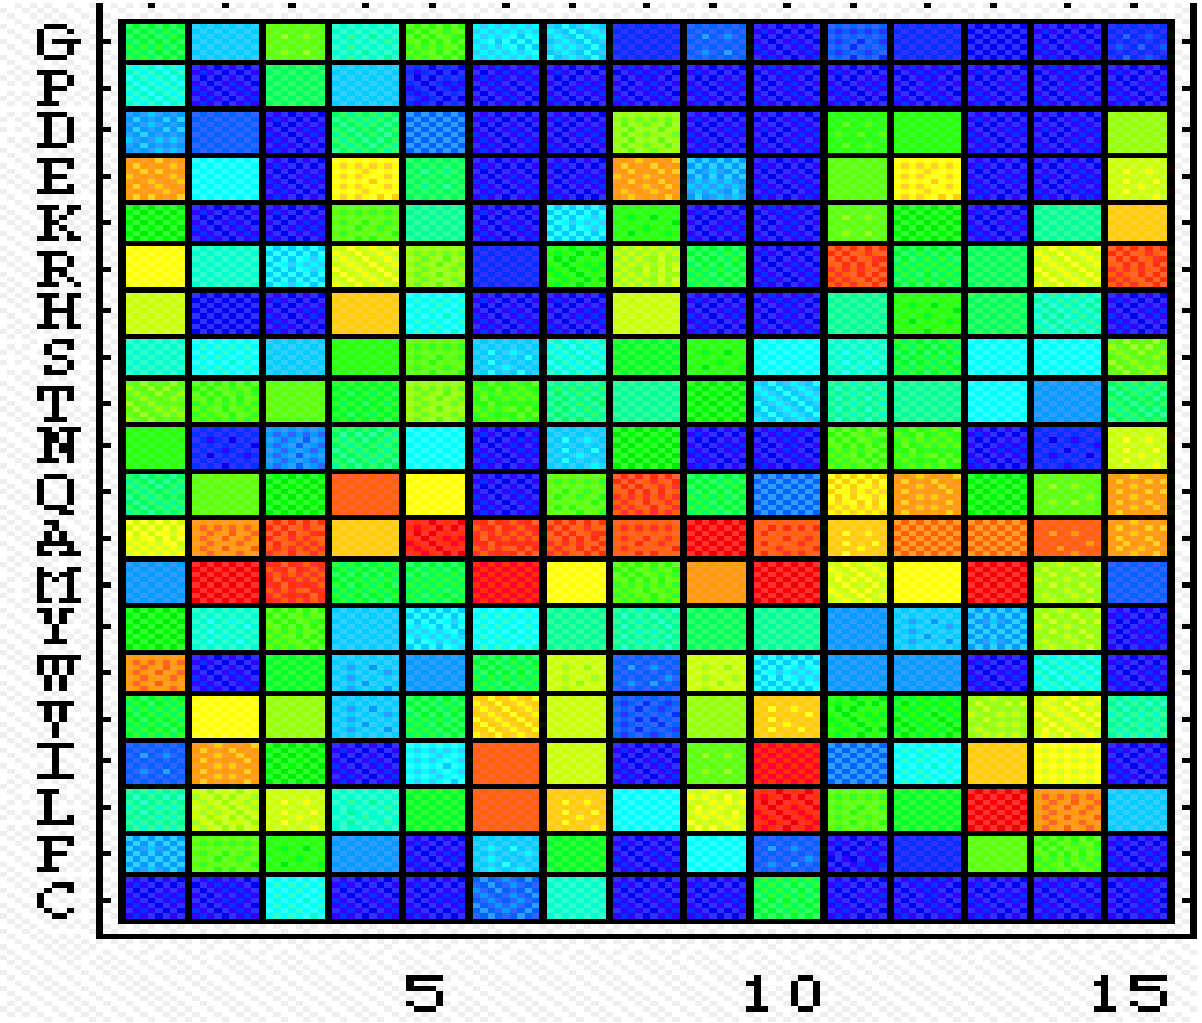
w_1
w_2
w_3
w_4
w_5
w_6
w_6
w_7
w_8
w_9
w_1
w_1

Sequences in the MSA are "weighted".



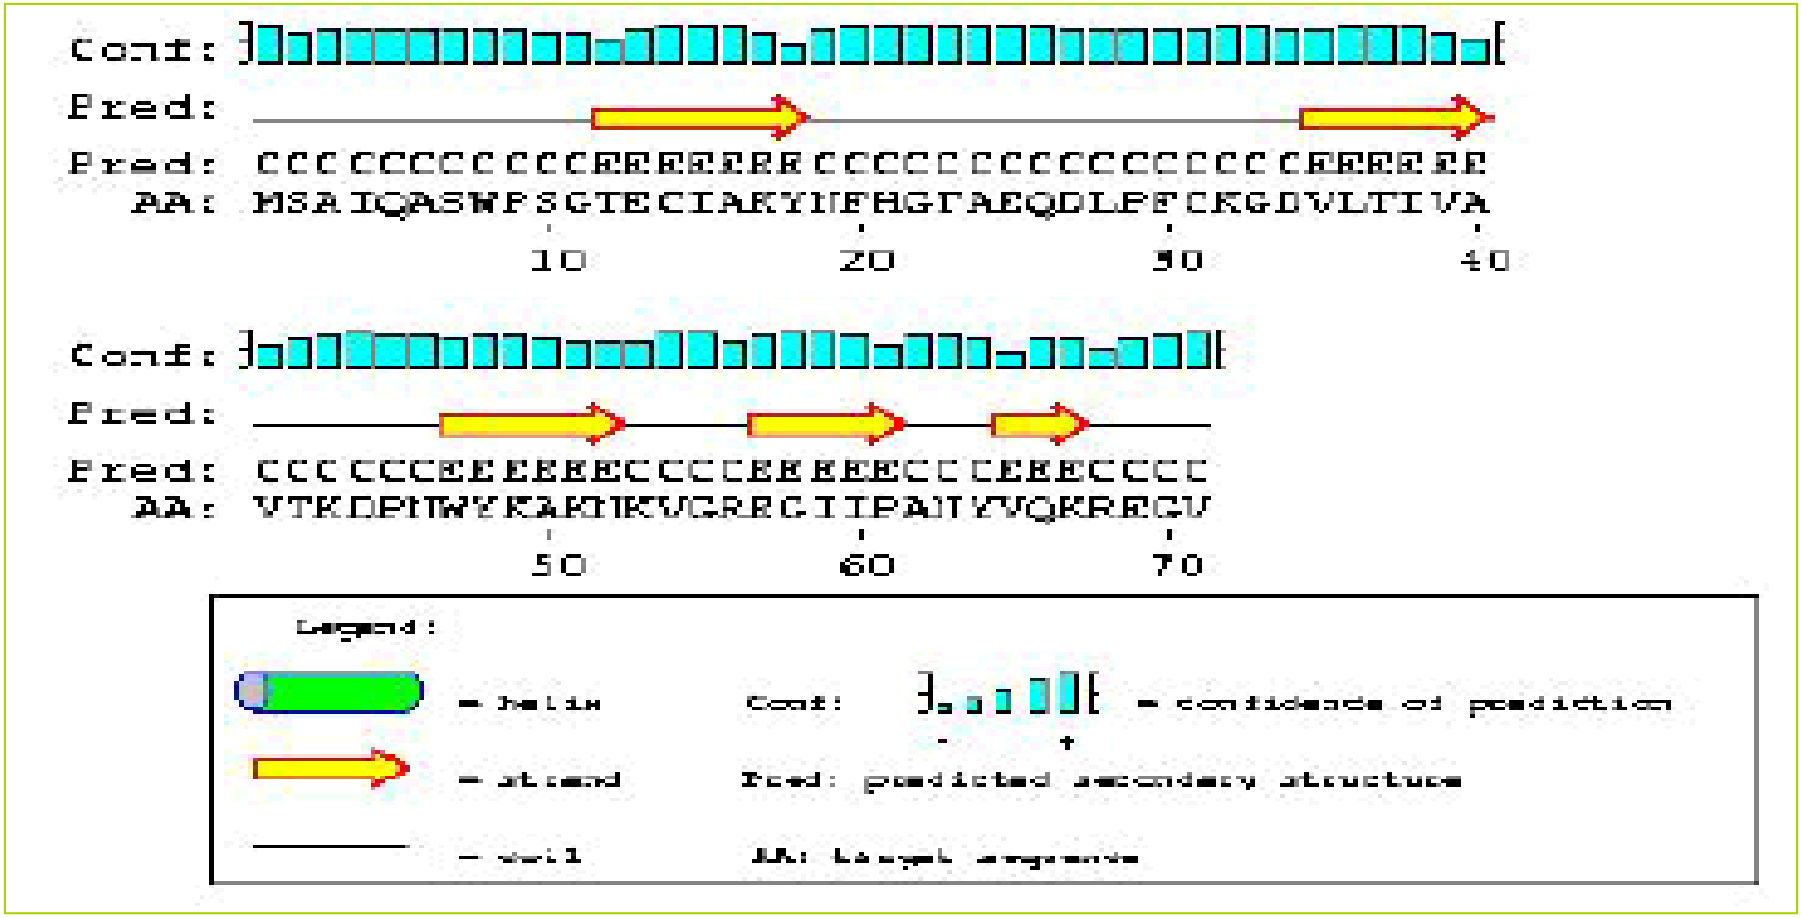
[The probability of amino acid *T* at position *7* is the sum of the sequence weights w_i over all sequences *i* such that the amino acid at position *7* of that sequence is *T*, divided by the sum over the sequence weights w_i.]

A sequence profile is a 20xN matrix of AA probabilities



PSI-pred-- secondary structure from **profiles**

• PSI-PRED (Jones et al.) is currently the best server for secondary structure prediction, based on an artificial neural network that connects a profile (**Psi-Blast** output) with known protein secondary structure Predictions are assigned *confidences*. A window of 15 is used to predict the central residue. Accuracy claimed to be 76-78%.

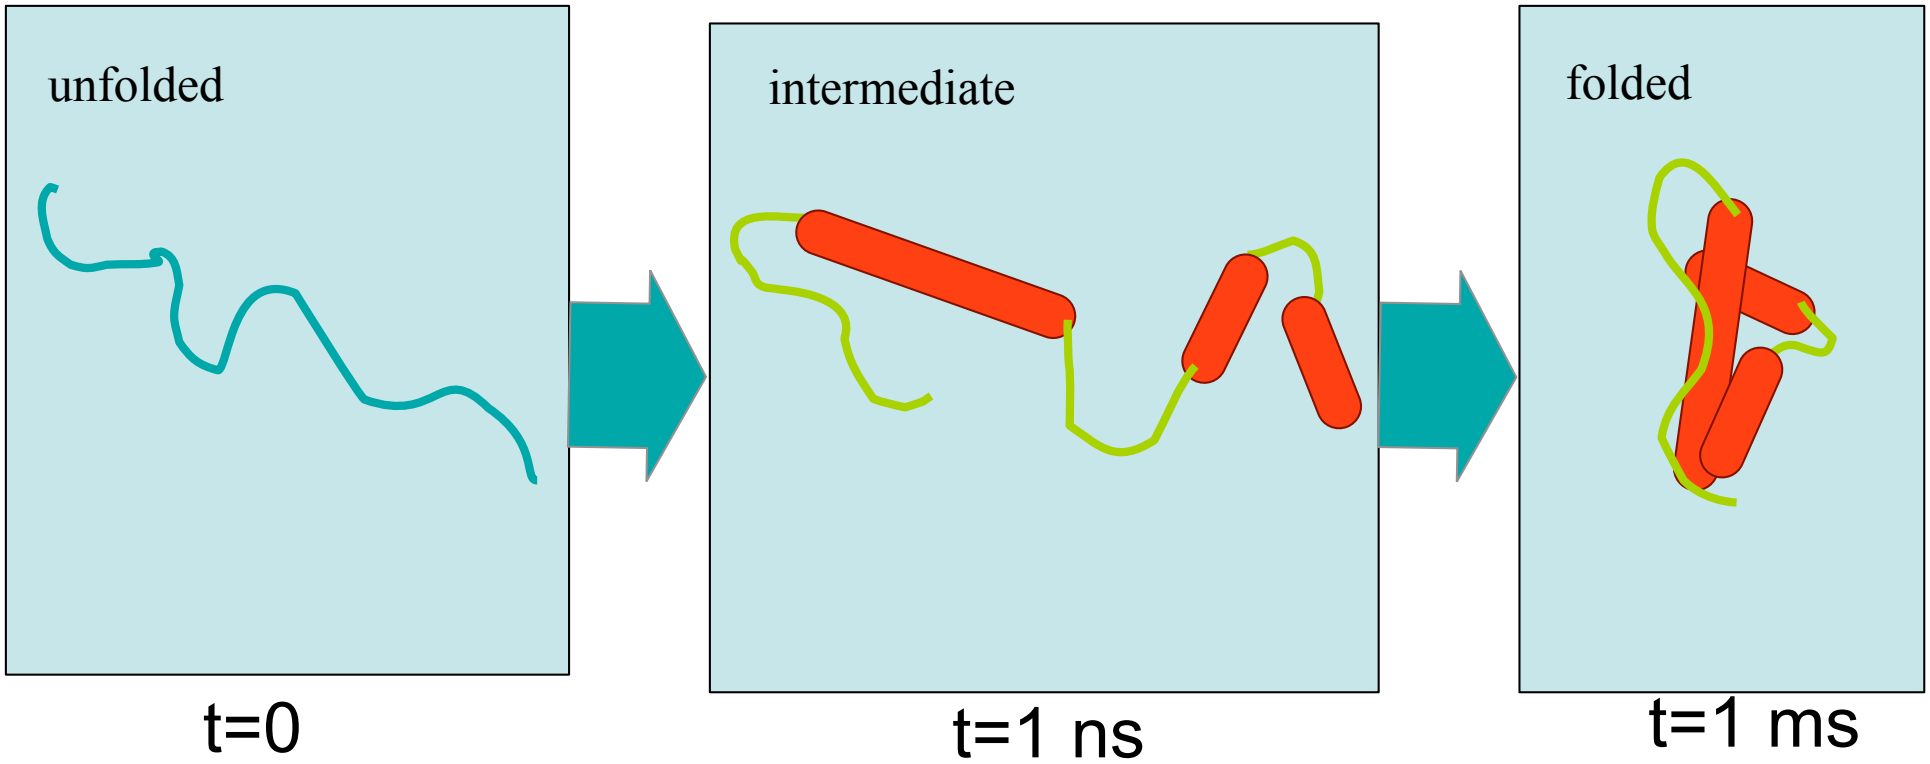


The PSIPRED protein structure prediction server L. J. McGuffin, K. Bryson, D. T. Jones (2000) *Bioinformatics* 16 (4) p. 404-405

Why does local sequence predict structure?

Early in the process of folding (nsec timescale)

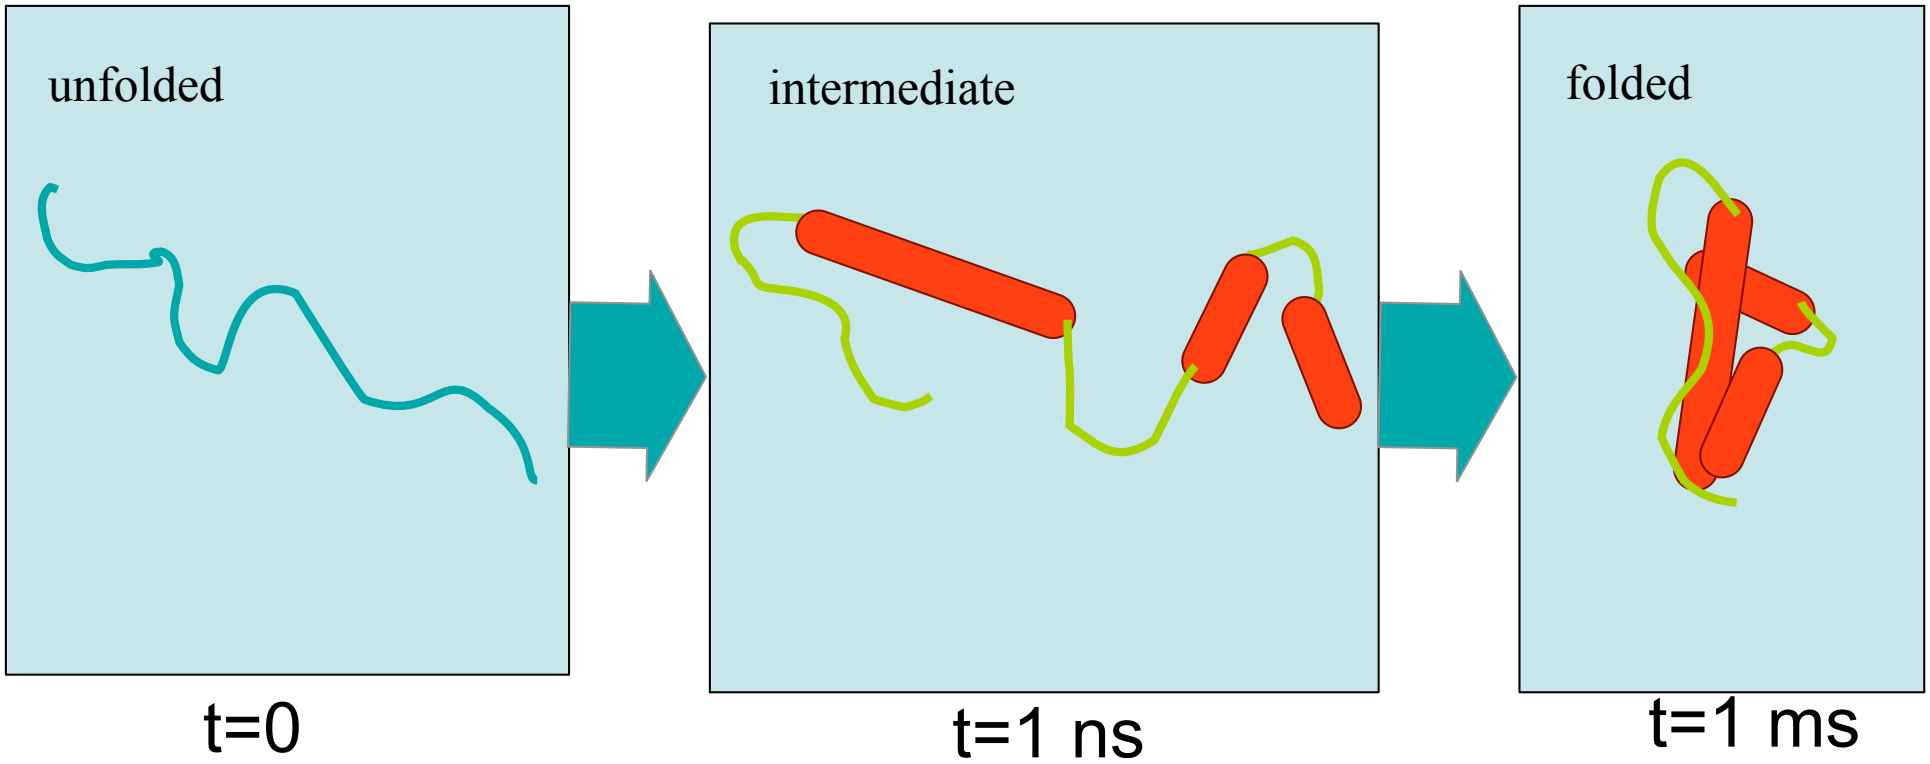
local structures form in the polypeptide chain which guide the formation of tertiary structure.



What is local structure?

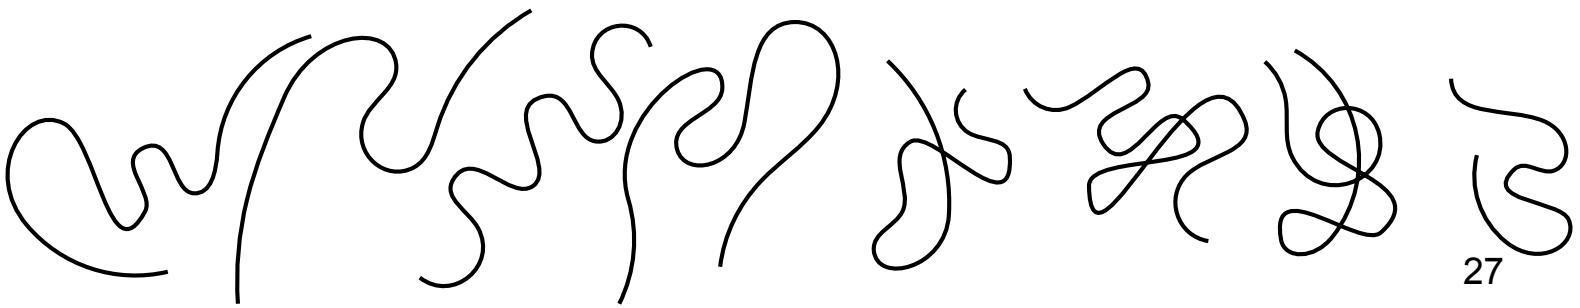
Early in the process of folding (nsec timescale)

local structures form in the polypeptide chain which guide the formation of tertiary structure.



Local structure formation

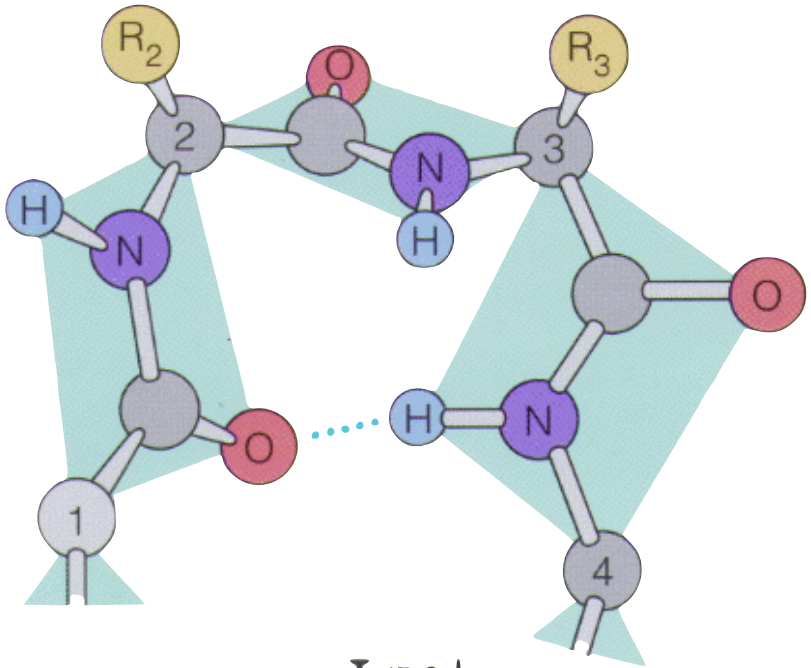
- Short pieces of protein sample conformational space randomly, driven by the hydrophobic effect (mostly).
- Glycines provide points of greater flexibility.



beta turns

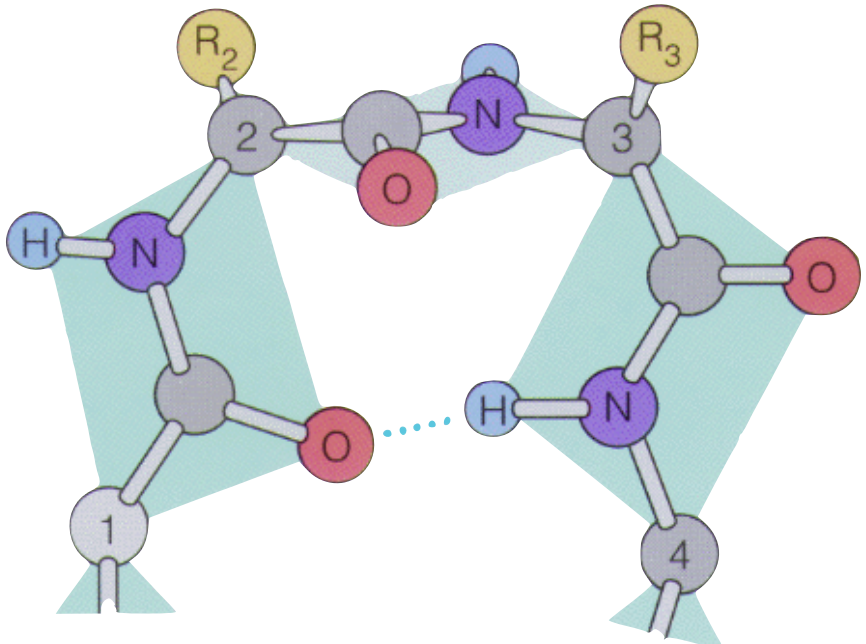
4-residues

Residue 1 hydrogen bonds to residue 4



Type I

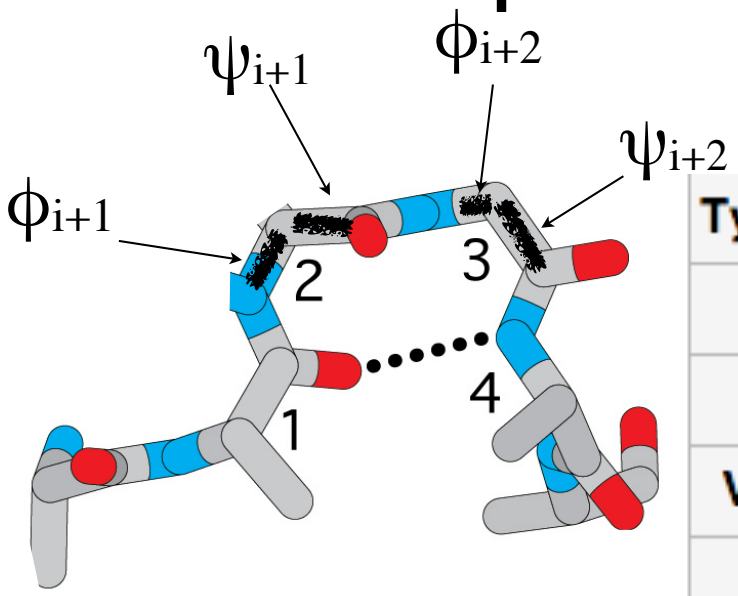
Type I (most common). Oxygen points away, viewed clockwise.



Type II

Type II (less common). Oxygen points toward, viewed clockwise.

Backbone angles and preferred sequence of beta turns



Glycine rules turn propensity

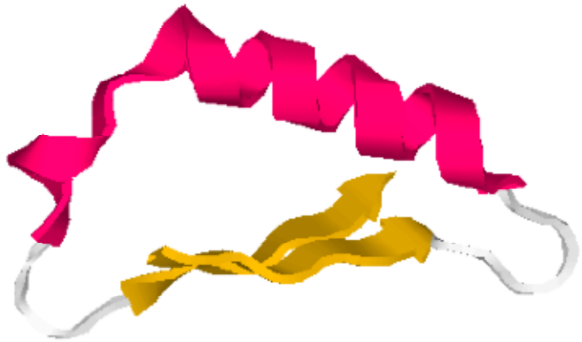
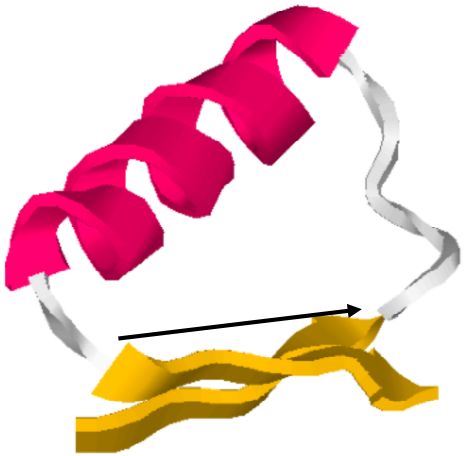
Super-secondary structure. αβ

βαβ supersecondary structure units are mostly right-handed





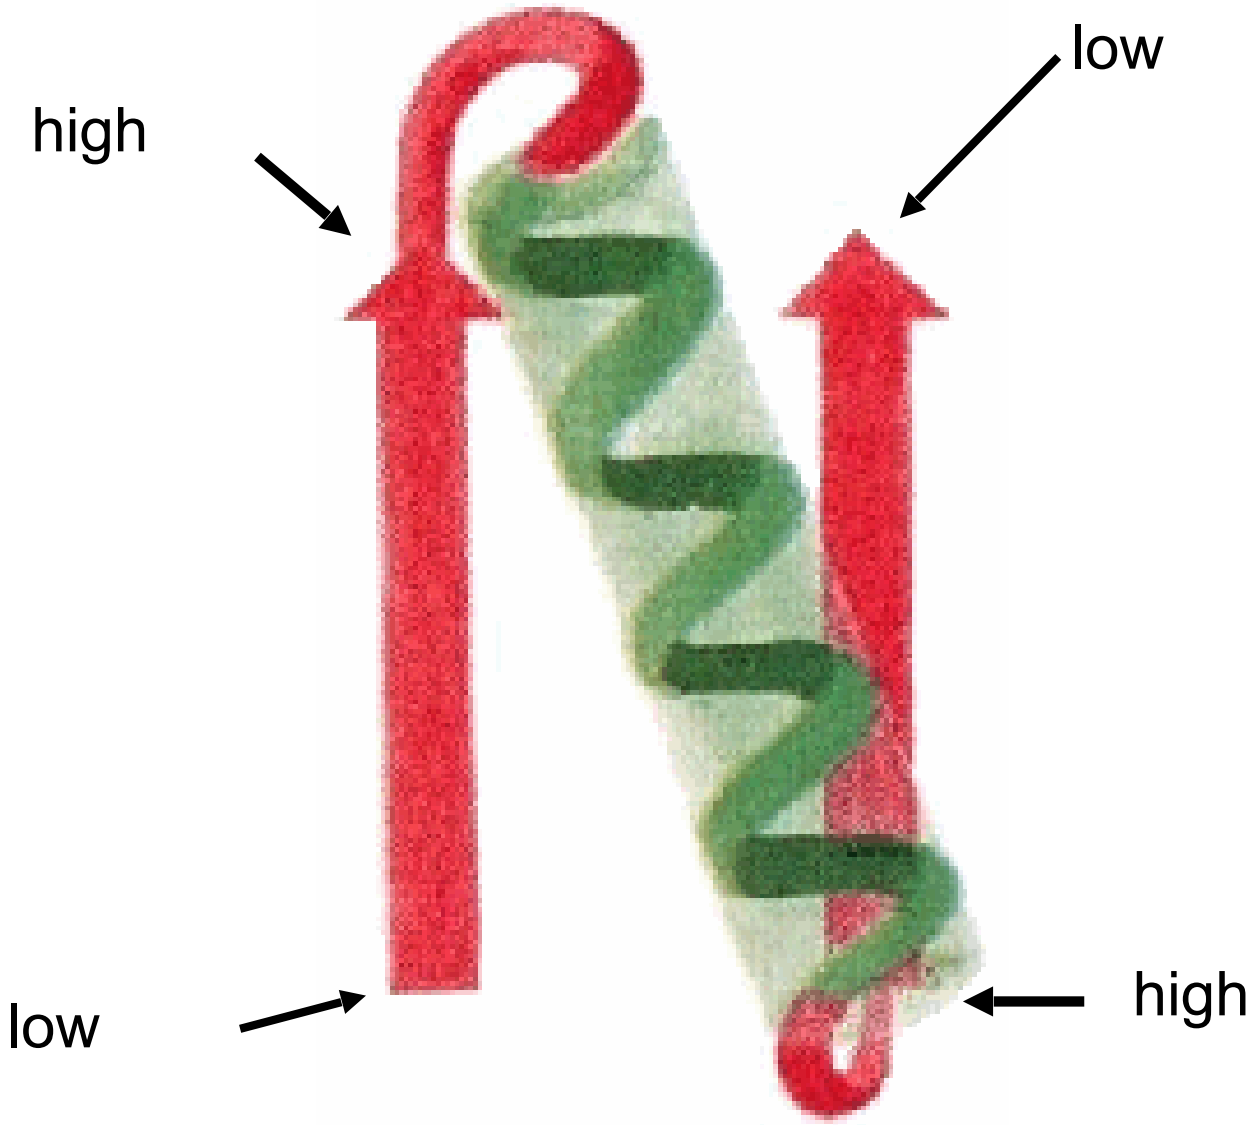
L-handed βαβ

1.5%

R-handed βαβ

98.5%

Theories for why βαβ units are right-handed.



Sternberg & Thornton: Twist of beta sheet makes right-handed crossover more of a straight line.

Theories for why βαβ units are right-handed.

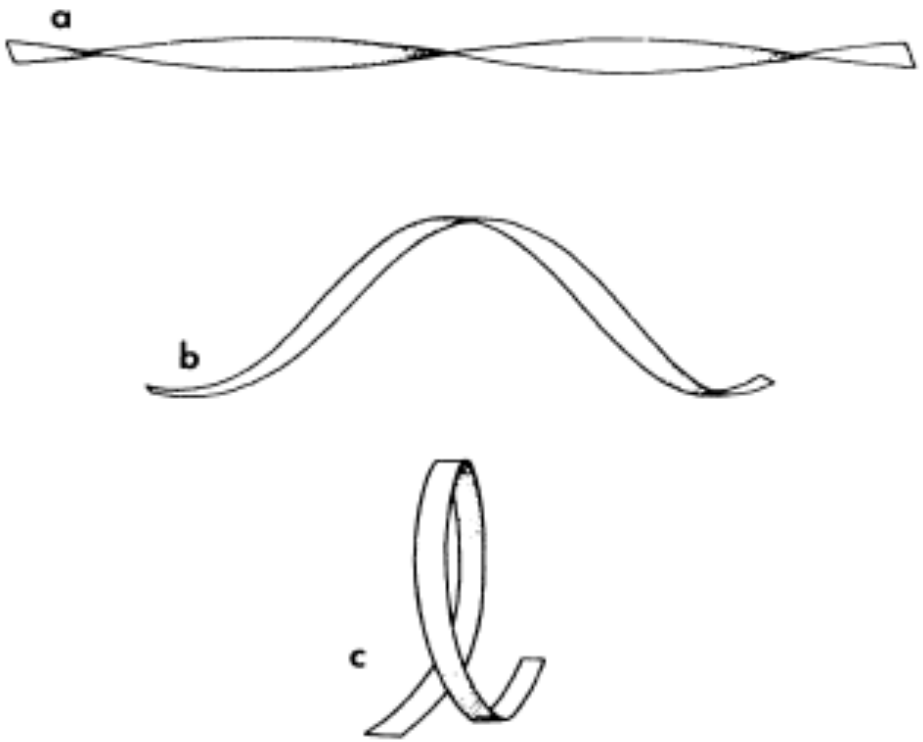


FIG. 4. A possible folding pathway which produces righthanded crossover loops from extended chain. In (a) the section of chain is extended, showing one full turn of the preferred righthanded twist for β strands. In (b) the two ends of this chain segment are moving toward one another, and the ribbon has started to buckle in a right-handed sense constrained by the chain twist. In (c) a complete righthanded loop is formed, with the two ends in position to form parallel β structure.

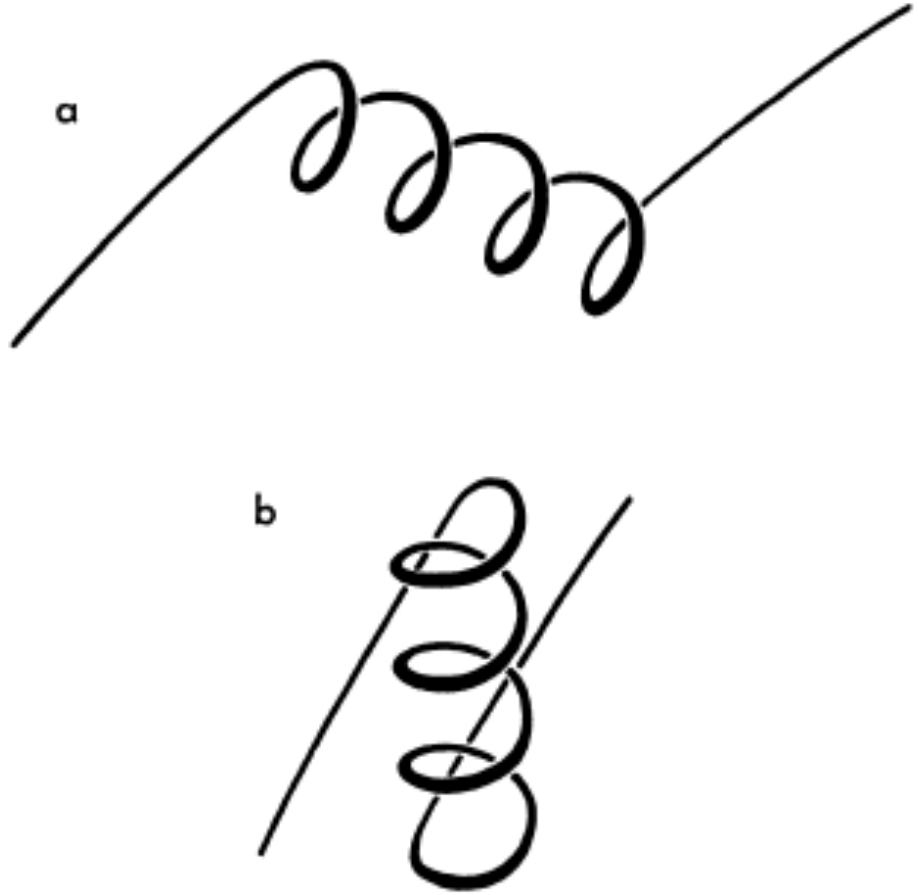

FIG. 5. A possible folding pathway which forms righthanded crossover loops from a righthanded α-helix with a β strand at each end of it.

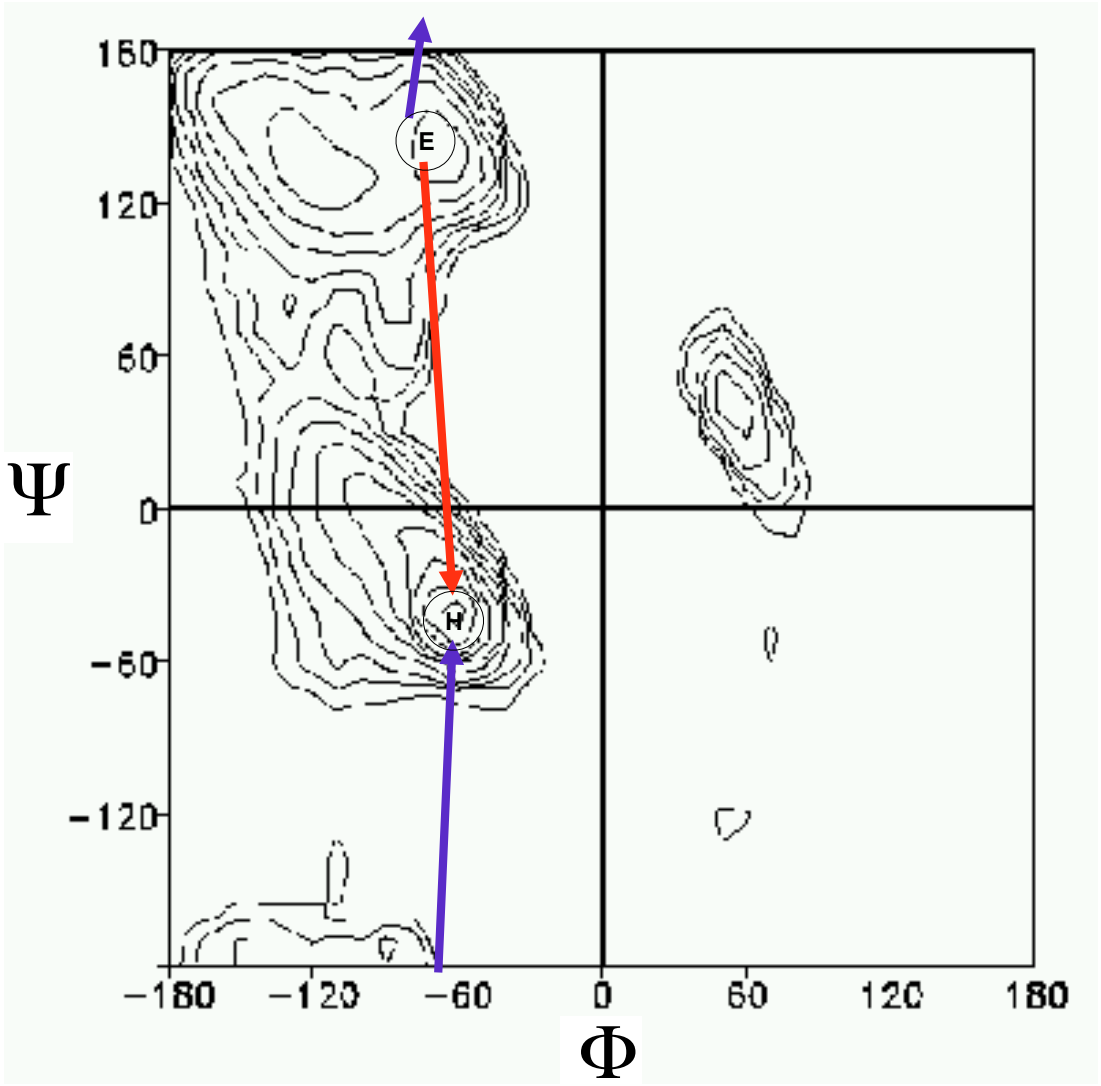
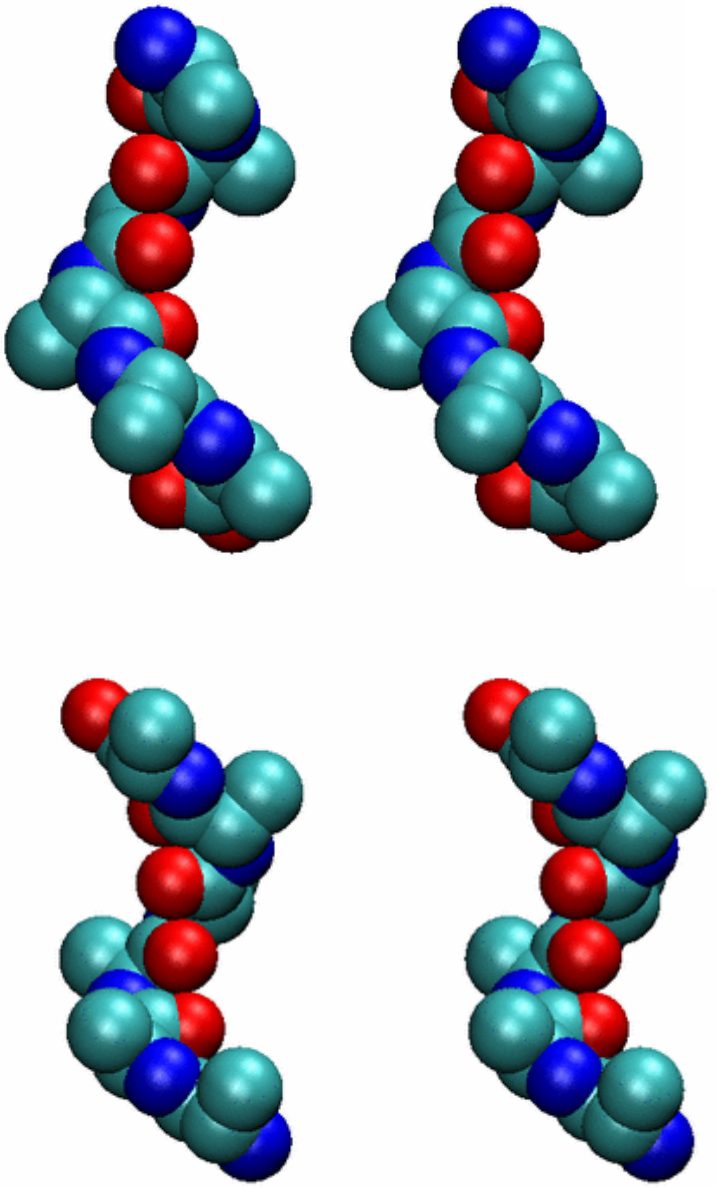
Richardson, PNAS, 1976: Right-handed crossovers are trapped early in folding

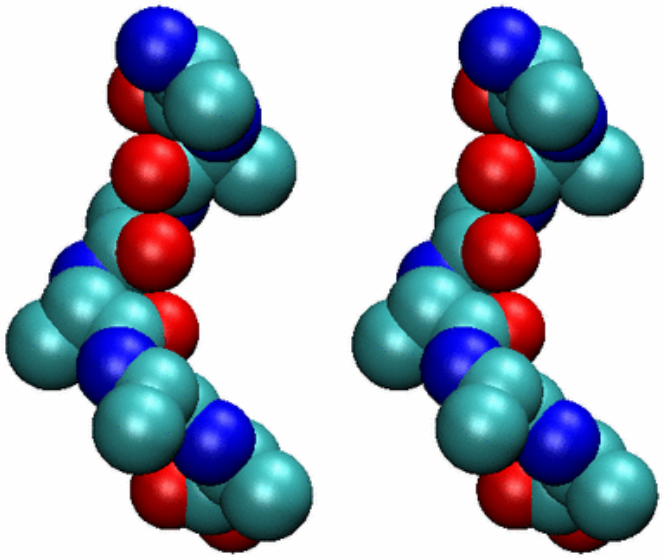
Theories for why βαβ units are right-handed.

Phone Cord Effect: Northern versus Southern route to helix

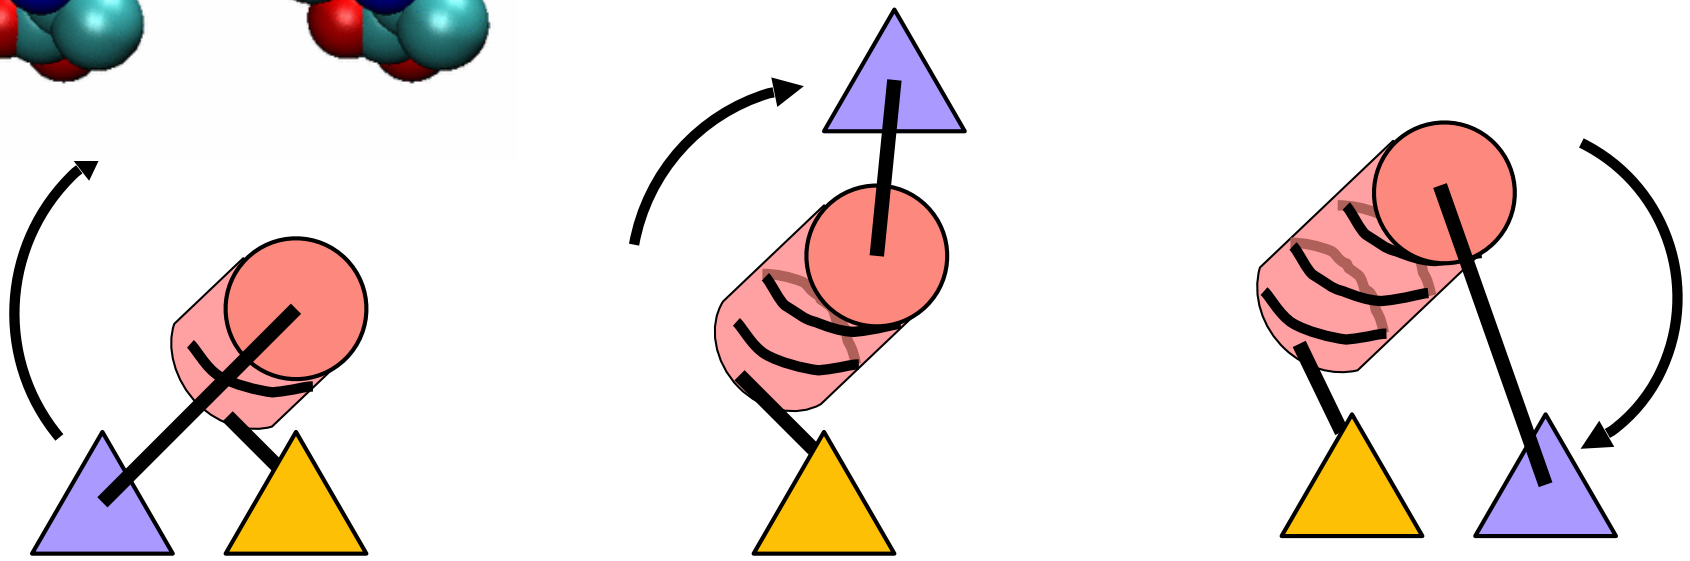




Cole B & Bystroff C. (2009) Alpha helical crossovers favor right-handed supersecondary structures by a kinetic trapping mechanism. The phone cord effect in protein folding. ***Protein Science*** **18(8) 1602 - 1608**



Theories for why βαβ units are right-handed.



LH ——————————————————— RH

left-handed torque turns left-handed βαβ to right-handed βαβ

How to force hydrogen bonds using restraints

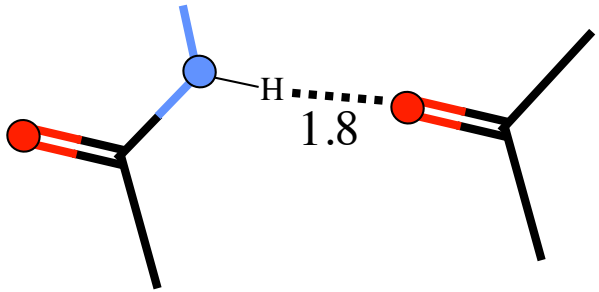
- To add a restraint
  Edit | Potential | Restrain, distance,
  Target 1.8, 1.8, Weight 50
  Pick amide H and carbonyl O.
  Click **Create**.
  Cancel | Restrain (or esc) when done
- Energy minimize

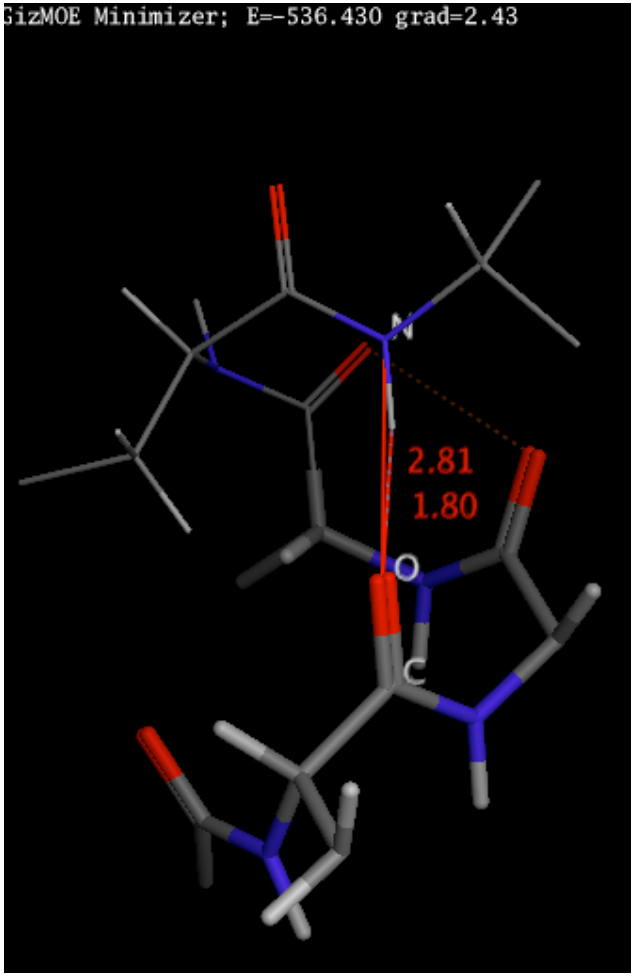
  Compute | prepare | Structure preparation

  Checks for missing atoms, assigns energies.

  SVL: run ‘gizmin.svl’

  When finished, be sure to **Cancel | GizMOE_Minimizer**
- To remove or modify restraints
  Potential setup (button at far lower left)
  Restraints tab





Exercise 18.2

Make a beta hairpin

anti-parallel sheet with valine side chains all on the same side of the sheet.

Edit | Build | Protein, Geometry: **anti-strand**. Residue: **ADVDVKVSPNGVEVKVRA**

Zoom out.

Select the second half of the chain starting with NG.

Rotate and translate it (**shift-alt-middlemouse**) so that the first three valines (3,5,7) are lined up with other there valines (12,14,16), and the valine backbone H-bonding groups (NH and CO) are close to the H-bonding distance (1.8Å from H to O)

Hide side chains to help see the backbone atoms better.

Edit | Potential | Restrain.
Set Target 1.8, 1.8, Weight 50. Select H and O atoms. **Create**.
When done you have 2 restraints for each of the three paired valines for a total of 6 restraints**.**

Compute | Prepare | Structure preparation. Hit **Correct** if necessary. **Protonate3D**.

SVL: run 'gizmin.svl'.

If there are errors in the restraints, **Cancel/GizMOE,** open **Potential Setup** (extreme lower left of the MOE window). **Restraints**. Click on restraints to delete or modify them.
Restart **SVL: run 'gizmin.svl'.**

Look at out the structure.
It should have beta pleating when viewed from the edge of the sheet. Sidechains should alternate up and down in that view.
Residues SPNG form a beta-turn.

Cancel/Gizmin . Remove the restraints. Restart **SVL: run 'gizmin.svl'**.

Does the structure hold together or fall apart?
